Abstract

Stable envelopes, introduced by Maulik and Okounkov, form a basis for the equivariant cohomology of symplectic resolutions. We study the case of Nakajima quiver varieties, where the resolution is a hyperkähler quotient. We relate the stable basis to that of the associated quotient by a maximal torus, and obtain a formula for the transition between the stable basis and the fixed point basis, using the root system and combinatorial data from the torus quotient.

We compute the transition matrix explicitly in the case of cotangent bundles to partial flag varieties, and show that for Grassmannians, it is given by rational Schur polynomials. This recovers in a geometric way the diagonalization of the Hamiltonian in the XXX spin chain. As a second application, we study the case of the Hilbert scheme of points on the plane, and obtain a novel formula expressing Schur polynomials in terms of Jack polynomials.
Acknowledgements

First and foremost, it is a pleasure to thank my thesis adviser, Andrei Okounkov. Andrei suggested the problem and many of the ideas contained in this work. More importantly, however, he has been a great adviser. Andrei generously supplied ample guidance, was always happy to meet and work together, and could explain the same thing over and over again with seemingly endless patience. He knew how to feed me just one bite more than I could chew and was always supportive, even when I stumbled. The countless pitchers of beer after the weekly seminars were also appreciated.

The work presented here stems from the author’s attempt to understand Andrei’s paper with Davesh Maulik, “Quantum groups and quantum cohomology”. I would like to thank Davesh for his interest in this work and for many conversations and explanations, which often supplied an intriguing point of view complementary to Andrei’s.

Much of this work is part of a joint project with Michael McBreen, a faithful friend and collaborator. Michael’s confident and creative way of thinking about mathematics has been a great source of inspiration and motivation, and he has taught me a great deal about math, physics, and deadpan humor.

During the course of our work, Michael and I have benefited from many fruitful conversations with colleagues; among many others, I would like to thank Tom Braden, Sachin Gautam, Alexei Oblomkov, and Nick Proudfoot. Special thanks to Andrey Smirnov for his interest in this work and for careful reading of the manuscript.

Jill Leclair, the department graduate administrator, was always happy to help with any question or request, starting from before I was even a prospective student. She has made navigating graduate school that much easier, and I thank her heartily. I would also like to thank Anna Wienhard, the director of graduate studies during most of my years in Princeton, for her support, help, and collaboration on departmental activities.
Jennifer Johnson made my teaching experience in Princeton particularly pleasurable. She has been extremely accommodating of my restricted schedule as a commuting student, and more importantly, made visible her appreciation and respect for my work. I have had the opportunity to work closely with Jennifer, a great learning experience for which I am grateful.

Alex Lubotzky of the Hebrew University was my Master’s advisor in Jerusalem. He not only introduced me to mathematics, but continued to serve as a source of support, encouragement, and mentorship throughout my Ph.D. studies, and it is my pleasure to thank him.

I am grateful to my many friends in the department for countless conversations and adventures, mathematical and otherwise, in varying degrees of sobriety. To my good fortune, they are too numerous to list here individually. Special thanks to all the Princeton folk who were always happy to extend an invitation for a place to crash, especially Ali Altug, Boris Alexeev, and the two Gabrieles, who have generously extended their welcome time and time again.

I am thankful to my family and friends who have been a source of comfort and made a difference despite the distance – which sometimes turned into an excuse to attend many interesting conferences – but mostly, for many years of love, friendship, and affection.

Last but certainly not least, to my wife Stephanie, who stood by me all the way from application to graduation, lovingly and devotedly putting up with all the trials and tribulations of graduate school – Thank you.

Chapter 1

Introduction

Let $X$ be a symplectic resolution, namely a smooth complex algebraic variety equipped with a holomorphic symplectic form $\omega$, which is a resolution of singularities. We will be interested in the situation where $X$ is obtained as a hyperkähler quotient by a reductive group $G$. This includes most cases of interest, in particular Nakajima quiver varieties. We will treat in detail two particular examples:

1. Cotangent bundles to type $A$ partial flag varieties;

2. The Hilbert scheme of points on $\mathbb{C}^2$.

In [22], Maulik and Okounkov introduce stable envelopes, which form a basis of lagrangian classes in $H^*_A(X)$, where $A$ is a torus whose action scales $\omega$ by a non-trivial character. In that paper, the stable basis is used as a tool for the computation of the operators of quantum multiplication by a divisor in quiver varieties, and as a basic ingredient in establishing important cases of the Nekrasov-Shatashvili correspondence [28, 27]: a deep connection between the algebra of quantum multiplication and the commuting quantum integrals of motion in an associated quantum integrable system.

In this work we will not be using the “quantum” part of the theory except as a motivation. In fact, we believe that the stable basis is of great interest in itself, being closely related to many key objects in representation theory and in mathematical
physics. For example, in case (1) above it is essentially given by characteristic cycles of Verma modules (see 2.2.3). In case (2), identifying the cohomology ring with the ring of symmetric polynomials, the stable basis corresponds to Schur polynomials (6.1.2).

The main focus of our work is computing the transition matrix between the stable basis and the fixed-point basis. It turns out that for this end it is very fruitful to study the abelian quotient, i.e. the quotient of the same space by the action of a maximal torus $T \leq G$. Hyperkähler quotients by a torus are called hypertoric varieties; much like toric varieties, their geometry can be described by combinatorial methods, in this case by using hyperplane arrangements. Smooth hypertoric varieties are symplectic resolution, and using their combinatorial description, we show in (3.3.5) how to explicitly express the stable basis in terms of certain tautological classes.

The next natural step is “abelianization”, namely relating the stable basis in $X$ to that of the abelian quotient. We describe this relation in our main theorem (4.3.1), and use it to obtain a formula (4.3.3) giving the restriction of the stable basis to fixed components. In particular, for any Nakajima quiver variety we have a constructive way of expressing the stable basis in the fixed point basis. We study in detail the two cases mentioned above and obtain explicit formulas. In the first case, and specifically for cotangent bundles to Grassmannians, we recover in a geometric way known results related to diagonalization of the Hamiltonian in the $XXX$ spin chain, as well as the restriction of Schubert classes to fixed points (5.3). For Hilb, the fixed point basis is given by suitably normalized Jack polynomials, and in (6.3.6) we obtain a novel formula expressing Schur polynomials in terms of Jack polynomials.

Relating the structures of abelian and non-abelian quotients has been the topic of several studies. In the hyperkähler setting, Hausel and Proudfoot [15] have studied the relation between their cohomology rings, relying on previous work by Martin [21] in the symplectic case, and Ellingsrud-Strømme [7] in the GIT setting; see also [1]
for conjectural relations between Gromov-Witten invariants in the Kähler case. We expect that the results presented here will prove useful in understanding the relation between the quantum cohomology of the abelian and non-abelian hyperkähler quotients, and complete descriptions for the quantum rings. This is the focus of ongoing work of the author with Michael McBreen; a first step, giving a full presentation of the quantum cohomology ring of hypertoric varieties, appears in [23].

From the point of view of the Nekrasov-Shatashvili theory, a notion of $K$-theoretic stable basis would be immensely useful. A definition for what a stable $K$-class may be has been proposed to us by Maulik and Okounkov, with the caveat that it is not clear how to prove the existence of the stable sheaf for a general symplectic resolution. Here once again we expect the abelianization procedure to prove useful: in the abelian case the stable sheaf is nothing but the structure sheaf of the stable envelope, and an analogous abelianization construction gives the stable sheaf and allows us to compute its restriction to fixed points. While the author has some preliminary results in this direction, they are not presented here.

The structure of this thesis is as follows. In chapter 2 we review a few facts about symplectic resolutions and define the stable basis. For context, we briefly review some of its applications in the Nekrasov-Shatashvili theory as presented in [22]. In chapter 3 we introduce hypertoric varieties and give some background on their geometry. We then show how to express the stable basis in terms of tautological classes and in the fixed point basis.

In chapter 4 we study the abelianization procedure for stable bases. We start by studying the geometric relation between abelian and non-abelian hyperkähler quotients, and use it to derive a formula for the restriction of the stable basis to fixed components. In chapters 5 and 6 we apply our formula to the two examples above. In particular, we obtain a new formula expanding Schur polynomials in the Jack basis.
Chapter 2

Stable Envelopes

2.1 Symplectic resolutions

2.1.1 Basic setting

We briefly review a few basic results on symplectic resolutions. A more detailed treatment can be found in [5] and the references within. A symplectic resolution $X$ is a holomorphic symplectic variety, such that the canonical map

$$\pi : X \to X_0 = Spec(H^0(X, O_X))$$

is projective and birational. We assume that $X$ admits an action by a reductive group $G = G \times \mathbb{C}^*$, satisfying the following conditions:

1. The $G$ action is Hamiltonian;

2. The $\mathbb{C}^*$ action scales the symplectic form by a nontrivial character $\hbar$;

3. The fixed point locus $X^g$ is proper for some $g \in G$.  

Deformation

The deformations of \((X, \omega)\) are classified by the period map, namely the image of the symplectic form \(\omega\) in \(H^2(X, \mathbb{C})\):

\[
\begin{array}{c}
X \xrightarrow{\phi} \tilde{X} \\
[\omega] \xrightarrow{} H^2(X, \mathbb{C})
\end{array}
\]  

(2.1)

The fibers of \(\phi\) are symplectic resolutions, and the generic fiber is affine. Primitive curve classes \(\beta \in H_2(X, \mathbb{Z})\) are only effective along hyperplanes in the base where the pairing \(\omega(\beta)\) vanishes; we call these root hyperplanes, and their union the discriminant locus. When \(X\) is a hyperkähler quotient, \(\tilde{X}\) is obtained by varying the level of the moment map, as explained in (4.1.1).

### 2.1.2 Nakajima quiver varieties

Arguably the most important family of symplectic resolutions, and the one we will be primarily interested in, is that of Nakajima quiver varieties. We give a brief description to fix notation; a more thorough introduction can be found in e.g. [10, 22, 25].

Let \(Q\) be a finite quiver with vertex set \(I\) and edges \(E\). Given dimension vectors \(v_i, w_i\) indexed by \(I\), define complex vector spaces \(V_i, W_i\) of corresponding dimensions, and let \(G = \prod_i \text{GL}(V_i)\). Let \(\theta\) be a character of \(G\) and \(\xi \in Z(g^*)\) a fixed point of the coadjoint action. Let

\[
\mathcal{V} = \bigoplus_{(i,j) \in E} \text{Hom}(V_i, V_j) \oplus \bigoplus_{i \in I} \text{Hom}(W_i, V_i).
\]

Identifying \(T^* \text{Hom}(V_i, V_j) = \text{Hom}(V_i, V_j) \oplus \text{Hom}(V_j, V_i)\), we write a point in \(T^* \mathcal{V}\) by
data \((X_{ij}, Y_{ij}, i, j)\) where
\[
X_{ij} \in \text{Hom}(V_i, V_j) \quad Y_{ij} \in \text{Hom}(V_j, V_i) \\
i_i \in \text{Hom}(W_i, V_i) \quad j_i \in \text{Hom}(V_i, W_i).
\]

Identifying \(g \cong g^*\) via the Killing form, the \(G\) action and the moment map \(\mu : T^*\mathcal{V} \rightarrow g^*\) are given by
\[
g(X, Y, i, j) = (gXg^{-1}, gYg^{-1}, gi, jg^{-1}) \\
\mu(X, Y, i, j) = \sum_{i \in I} [X, Y] + ij
\](2.2)

We now define the Nakajima variety \(\mathcal{M}_{\theta, \xi}\) to be the hyperkähler quotient
\[
\mathcal{M}_{\theta, \xi} = T^*\mathcal{V} \sslash \theta \mathcal{G} = \mu^{-1}(\xi)^{\theta-ss}/\mathcal{G}
\]
where \(\theta\)-ss denotes the \(\theta\)-semistable points and we take the GIT quotient. For generic values of \(\theta\), \(\mathcal{M}_{\theta, \xi}\) is smooth, hence a symplectic resolution. When \(\xi = 0\), the \(\mathbb{C}^*\) action scaling the fibers of \(T^*\mathcal{V}\) descends to the quotient and our basic assumptions are satisfied. The following well-known examples are treated in detail in chapters 5, 6.

**Example 2.1.1.** Let \(Q\) be a type A quiver with vertices 1..r and edges between adjacent vertices. Let \(k_1 < k_2 < \ldots < k_r < n\)

and put \(v = (k_1, \ldots, k_r, w = (0, \ldots, 0, n).\) Choosing the character \(\theta = \prod \text{det}, \mathcal{M}_{\theta, 0}\) is the cotangent bundle to the variety of partial flags of dimensions \(k_1, \ldots, k_r\) in \(\mathbb{C}^n\).

**Example 2.1.2.** Let \(Q\) be the Jordan quiver with one vertex and one loop from the vertex to itself, and put \(v = n, w = 1.\) Choosing again \(\theta = \text{det}, \mathcal{M}_{\theta, 0}\) is the Hilbert scheme of \(n\) points on \(\mathbb{C}^2\).
Hypertoric varieties and abelianization

Another family of symplectic resolutions which will be important to us is that of \textit{hypertoric varieties}, introduced in more detail in the next chapter. These are the hyperkähler quotients $T^*V//T$ where $V$ is a complex vector space and $T$ is a torus. Smooth hypertoric varieties are symplectic resolutions.

For a Nakajima quiver variety $\mathcal{M} = T^*V//G$, we can construct the hypertoric variety $T^*V//T$, where $T$ is a maximal torus of $G$. We call this the \textit{abelianization} of $\mathcal{M}$. The relation between $\mathcal{M}$ and its abelianization is of primary interest to us.

2.2 The stable basis

Let $X$ be a smooth algebraic variety admitting an action by an algebraic torus $A$. Restriction to the fixed locus $X^A$ gives a map in equivariant cohomology:

$$res : H^*_A(X) \to H^*_A(X^A).$$

The idea of the stable basis is to construct, for a symplectic resolution, a canonical map in the other direction. We assume:

1. $X^A$ is proper;

2. $X$ is a formal $A$ variety (see e.g. [11]).

These assumptions will hold in all cases of interest. We denote by $A_0 \leq A$ the stabilizer of $\omega_X$ in $A$, and by $\mathfrak{a}, \mathfrak{a}_0$ the Lie algebras of $A, A_0$ respectively. In general, we denote by $F_A(X)$ the set of fixed components of the $A$ action on $X$. The reference for this section is [22], chapter 3. We first establish a few preliminaries.
2.2.1 Basic constructions

Chamber decomposition

The cocharacters $\sigma : \mathbb{C}^* \to A_0$ form a full rank integral lattice in $a_0$. Put $a_0^\mathbb{R} = \text{Cochar}(A_0) \otimes_{\mathbb{Z}} \mathbb{R}$. The normal bundle to any component of $X^{A_0}$ splits as a sum of $A_0$-equivariant line bundles, whose weights define hyperplanes in $a_0^\mathbb{R}$. Their union over all fixed loci divides $a_0^\mathbb{R}$ into open chambers $C_i$. If a cocharacter $\sigma$ lands in a chamber, then $X^\sigma = X^{A_0}$.

Stable leaves

Fix a chamber $\mathfrak{C}$ and a cocharacter $\sigma : \mathbb{C}^* \to A_0$ landing in it, and let $Z \in F_{A_0}(X)$. The leaf of $Z$ is defined as its attracting locus

$$m_X(Z) = \{x \in X : \lim_{t \to 0} \sigma(t) \cdot x \in Z\}.$$ 

This is a vector bundle over $Z$. We sometimes use the notation $m(X, Z)$, or suppress $X$ when no confusion may arise. We denote the closure of $m_X(Z)$ by $\overline{m}_X(Z)$. There is a partial order on $F_{A_0}(X)$, defined as the transitive closure of the relation

$$\overline{m}(Z) \cap Z' \neq \emptyset \Rightarrow Z \leq Z'.$$

If $X$ is affine, this ordering is trivial: $m_X(Z)$ is already closed. Define the slope of $Z$ by

$$\text{slope}(Z) = \bigcup_{Z' \geq Z} m(Z').$$

The slope is closed in $X$ ([22], 3.2.7). We say that a class $\gamma \in H^*_A(X)$ is supported on $\text{slope}(Z)$ if $\gamma|_{X \setminus \text{slope}(Z)} = 0$ in $H^*_A(X \setminus \text{slope}(Z))$; equivalently, as a Borel-Moore class, $\gamma$ is pushed forward from $\text{slope}(Z) \hookrightarrow X$. Here and in what follows we use the restriction symbol to denote the natural restriction maps in equivariant cohomology.
Polarization

For $Z \in F_{A_0}(X)$, we have an $A$-invariant decomposition of the normal bundle $N_XZ$,

$$N_XZ = N_+ \oplus N_-$$

into the $A_0$-weights on which $\sigma$ is positive or negative respectively. The symplectic form yields an identification

$$N_+ = N_\sigma^\vee \otimes \hbar$$

so that the $A_0$ equivariant Euler class $e(N_XZ)$ is a perfect square. A choice of $\varepsilon_Z$ for each $Z$ such that $\varepsilon_Z^2 = e(N_XZ)$ is called a polarization of the symplectic resolution. Note that

$$\text{leaf}(Z)|_{Z} = \pm \varepsilon_Z.$$

While the choice of a polarization is arbitrary, certain choices are geometrically natural and save on signs. If $X$ is a cotangent bundle, we can choose the polarization defined by the zero section. If $X$ is a hyperkähler quotient $T^*V/\!/G$, it admits a polarization induced by the natural polarization on $T^*V$.

Degree in $A_0$

Since $A_0$ acts trivially on $X^{A_0}$, we have

$$H^*_A(X^{A_0}) = H^*_h(X^{A_0}) \bigotimes_{\mathbb{C}[\hbar]} \mathbb{C}[a];$$

where $H^*_h$ stands for $A/A_0$ equivariant cohomology. Here and in what follows, all cohomologies are taken with complex coefficients unless otherwise indicated. Though this is immaterial to us, we note that for symplectic resolutions, all odd cohomologies
vanish. Any splitting

$$\mathbb{C}[a] \cong \mathbb{C}[a/a_0] \otimes \mathbb{C}[a_0]$$

leads to the same filtration on $H^*_A(X_{A_0})$, defining the $A_0$-degree.

### 2.2.2 Definition of the stable basis

For $Z \in F_{A_0}(X)$, the idea of the stable envelope is to construct a class supported on the slope, and lowering the equivariant $A_0$ degree. More formally,

**Theorem 2.2.1** ([22], 3.3.4). Let $X$ be a symplectic resolution, and fix a chamber $\mathcal{C}$ and a polarization $\varepsilon$. There exists a unique map of $H^*_A(pt)$ modules

$$stab : H^*_A(X_{A_0}) \to H^*_A(X)$$

depending on $\mathcal{C}, \varepsilon$, called the stable map satisfying the following conditions for any $Z \in F_{A_0}(X), \gamma \in H^*_h(Z)$:

- (support) $\text{stab}(\gamma)$ is supported on $\text{slope}(Z)$;
- (normalization) $\text{stab}(\gamma)|_Z = \pm \varepsilon_Z \cap \gamma$, with sign according to $\varepsilon$;
- (degree) $\text{deg}_{A_0} \text{stab}(\gamma)|_{Z'} < \frac{1}{2} \cdot \text{codim}_X Z'$, for all $Z' > Z$.

In particular, $\text{res} \circ \text{stab} : H^*_A(X_{A_0}) \to H^*_A(X_{A_0})$ is given by an upper-triangular matrix in the ordered fixed point basis, and we therefore obtain a basis for cohomology. We also use the terms stable envelope and stable basis, with the former typically indicating the Borel-Moore cycle. The degree condition follows from the following stronger condition:

- (divisibility) $\text{stab}(\gamma)|_{Z'}$ is divisible by $h$ for all $Z' > Z$. 

10
The construction of the stable basis is done by successive corrections: for \( Z, Z' \in F_A(X) \) with \( Z \cap m(Z') \) nonempty, one shows that an appropriate integral multiple of \( m(Z') \) can be added to \( m(Z) \) in a way that the degree condition is satisfied. The construction continues by induction for the next fixed components. In fact, the stable basis is given by a Lagrangian correspondence:

**Proposition 2.2.2** ([22], 3.5.1). There exists an \( A \)-invariant Lagrangian cycle \( L_c \) on \( X \times X^{A_0} \), proper over \( X \), such that \( \text{stab} \) is the induced correspondence \( H^*_A(X^{A_0}) \to H^*_A(X) \).

### 2.2.3 Stable envelopes via deformation

The good deformation properties of symplectic resolutions provide a useful geometric characterization of the stable basis. The reference for this subsection is [22], 3.7.

Choosing a line in \( B \subset H^2(X) \), generic in the sense that it does not intersect the discriminant locus away from the origin, we obtain from the diagram 2.1 a family over \( \mathbb{C} \) whose fibers away from 0 are affine, and so that the \( A \) action extends to \( \tilde{X} \). Put \( \tilde{X}^0 = \tilde{X} \setminus X \). For \( Z \in F_{A_0}(X) \), let \( \tilde{Z} \in F_{A_0}(\tilde{X}) \) be the component satisfying \( \tilde{Z} \cap X = Z \), and finally let \( \tilde{Z}^0 = \tilde{Z} \cap \tilde{X}^0 \).

Since the fibers away from zero are affine, \( m(\tilde{X}^0, \tilde{Z}^0) \) is closed in \( \tilde{X}^0 \). Specializing this cycle to the central fiber, we obtain an algebraic cycle in \( X \); as a Borel-Moore cycle, this is precisely \( \text{stab}_X(Z) \). Indeed, the divisibility condition follows at once since we are specializing a cycle that restricts to 0 on all fixed components other than \( \tilde{Z}_0 \). This construction does not depend on the choice of the deformation. As a correspondence, the stable map is thus given by specializing the leaf of the diagonal

\[
\Delta^0 \subset \tilde{X}^0 \times_{B^0} (\tilde{X}^0)^{A_0}.
\]  

(2.3)
2.2.4 Stable envelopes in cotangent bundles

Suppose that $X = T^*M$ for some projective variety $M$ on which $A_0$ acts with isolated fixed points. Let $A = A_0 \times \mathbb{C}^*$, with the induced symplectic action by $A_0$ and $\mathbb{C}^*$ acting by scaling the fibers with weight $h$.

Choose a chamber in $A_0$ and let $z \in M^{A_0}$ be a fixed point and $\mathcal{C}_{m(M,z)}$ be the structure sheaf over its leaf. Then as a Borel-Moore cycle,

$$\text{stab}_X(z) = CC(\iota_!(\mathcal{C}_{m(M,Z)})),$$

where $CC$ denotes the characteristic cycle (see e.g. [9] for the definition), and $\iota$ is the inclusion in $M$. To see this, recall that the characteristic cycle is supported on the closures of conormals bundles to the orbits in $\mathcal{D}(M, Z)$ and the multiplicity of $T^*_m(M, Z)$ itself is 1, hence the support and normalization conditions. For the degree condition, we note that each successive correction can be described as a specialization from a family of cycles in $X^0 = X \setminus M$ [9], and the previous argument holds.

**Example 2.2.3.** Let $G$ be a reductive group, $P$ a parabolic subgroup, $X = T^*G/P$. Let $\sigma$ be a cocharacter of a maximal torus. Then stable leaves are conormal bundles to Schubert cells, and the stable envelope is the characteristic cycles of a Verma module.

We remark that in general, the transition from the conormal (leaf) basis to the stable basis is not given by Kazhdan-Lusztig numbers as one might expect, because the characteristic cycle of the irreducible intermediate extension is not necessarily irreducible [2]. This is true, however, for Grassmannians [6].
2.3 Stable envelopes and the Nekrasov-Shatashvili Correspondence

The stable basis was introduced in [22] by Maulik and Okounkov to study the Nekrasov-Shatashvili correspondence and the operators of quantum multiplication for Nakajima quiver varieties. While we believe that the stable basis is of independent interest, and this correspondence is not directly related to the work presented here, we give a brief summary of a few of the ideas presented there in order to illustrate the role of the stable basis in the general theory.

2.3.1 Stable envelopes and Steinberg Correspondences

Let $X = \mathcal{M}(w) = \sqcup_v \mathcal{M}(v, w)$, and $X_0 = \mathcal{M}_0(w)$ be its affinization. The Steinberg variety of $X$ is defined as $Z = X \times_{X_0} X$. By a theorem of Kaledin, the irreducible components of $Z$ are all half-dimensional. They act as lagrangian correspondences on $H^*_G(X)$; we call them Steinberg correspondences.

For a divisor $u$ on $X$, a very general argument presented in [5] shows that the operator of quantum multiplication by $u$ is given by

$$u \ast = u \cap + \hbar \sum_{\beta} (u, \beta) f(q^\beta) Z_\beta(-),$$

where $\beta \in H_2(X)$ varies over effective primitive curve classes in $X$, $f$ is a power series and $Z_\beta$ is a Steinberg correspondence. Computing the operators of quantum multiplication therefore boils down to understanding the action of Steinberg correspondences. The stable basis enables us to localize this action in the following sense. Let $w = \sum_{i=1}^n w_i$ be any decomposition. Let $A_0$ be the torus acting with weight
on the corresponding subspace \( W_i \leq W \). Every component of \( X^{A_0} \) is a symplectic resolution, in fact a product of Nakajima varieties with framing vectors \( w_i \). Let \( \iota : Z \to X \) be the inclusion of such a component, \( \varepsilon \) a polarization of \( Z \). Then we have

**Proposition 2.3.1** ([22], 3.4.2). For any \( A_0 \)-invariant Lagrangian class \([L]\) on \( X\), there exists a unique Lagrangian cycle \( \text{Res}_Z L \) supported on \( L \cap Z \) called the residue of \( L \), such that

\[
\iota^*[L] = \varepsilon[\text{Res}_Z L] + ...
\]

where dots stand for terms of lower \( A_0 \) degree.

Let \( \Theta \) be a Steinberg correspondence, and \( \Theta^A \) its residue on the Steinberg variety of \( X^{A_0} \). Then we have the following commutative diagram ([22], 4.6.1):

\[
\begin{array}{ccc}
H^*(X^{A_0})_{\text{stab}} & \longrightarrow & H^* X \\
\downarrow \Theta^A & & \downarrow \Theta \\
H^*(X^{A_0})_{\text{stab}} & \longrightarrow & H^* X
\end{array}
\] (2.4)

This is a key result in the identification of the operators of quantum multiplication by a divisor given in [22], 10.2.1.

### 2.3.2 Stable envelopes and Yangians

On the quantum-integrable side, the authors of [22] construct a certain geometric Yangian, acting on \( H^*_G(M(w)) \), and identify the algebra of quantum multiplication with the commutative Baxter subalgebras generated by transfer matrices. Naturally, the \( R \)-matrix plays a central role in this theory, and its construction rests on the definition of the stable basis.

For a symplectic resolution \( X \) and a chamber \( \mathfrak{c} \), the map

\[
stab_{\mathfrak{c}} : H^*_A(X^{A_0}) \to H^*_A(X)
\]
becomes an isomorphism after inverting $e(N_-)$, and we can define the $R$-matrix

$$R_{e' e} = stab_{e'}^{-1} \circ stab_{e} \in \text{End}(H^*_A(X^{A_0})) \otimes \mathbb{Q}(a).$$

The Yang-Baxter equation is an easy consequence of this definition. The reader will note that our interest in restricting $stab$ to fixed points amounts to “computing half the $R$-matrix”. Theorem (2.4) shows that the Steinberg algebra intertwines $R$ matrices.

For any decomposition $w = \sum w_i$ as above we have a decomposition

$$H^*_A(M(w)) = \bigotimes H^*_A(M(w_i)).$$

and we obtain a collection of $R$ matrices

$$R_{ij}(a_i - a_j) \in \text{End} (H^*_A(M(w_i)) \otimes H^*_A(M(w_j))) \otimes \mathbb{Q}(a)$$

satisfying the Yang-Baxter equation. In this setting, a general construction identifies the Yangian as a subalgebra of $\text{End} (H^*_A(M(w)))$ generated by the $u \to \infty$ matrix coefficients of $R$-matrices applied to an auxiliary space ([22], 5.2). One can also identify Baxter subalgebras in the Yangian, also called Bethe subalgebras, generated by the commuting transfer matrices. These are the subalgebras which Maulik-Okounkov theory identifies with the quantum algebra of $M(w)$. A key ingredient of this identification are certain shift operators, which on the one hand are identified as quantum operators, and on the other hand their conjugation by $stab$ recovers the action of the $R$ matrix, again showing the central role played by the stable basis.
Chapter 3

The Stable Basis in Hypertoric Varieties

In this chapter we study the stable basis for abelian hyperkähler quotients. After reviewing the definitions of hypertoric varieties and their associated hyperplane arrangements, we show how to read off stable leaves and stable envelopes from the arrangement. We then express the stable basis in terms of tautological classes defined below. As a result, we obtain expressions for the stable basis in terms of the fixed-point basis in a purely combinatorial way.

3.1 Hypertoric Varieties

3.1.1 Definitions

We review here the definition and properties of hypertoric varieties which we will need in the sequel. A fuller treatment may be found in e.g. [29] and the references therein. Consider the torus $T^n = (\mathbb{C}^*)^n$ acting symplectically on $T^*\mathbb{C}^n$. Setting $t^n = \text{Lie}(T^n)$,
the moment map $\mu_n : T^*\mathbb{C}^n \to (\mathfrak{t}^n)^*$ is given by

$$\mu_n(z, w) = (z_1 w_1, ..., z_n w_n).$$

Let $T^k \leq T^n$ be an algebraic subtorus, $T^d = T^n / T^k$ \((d = n - k)\), and let $\mathfrak{t}^k, \mathfrak{t}^d$ be their respective Lie algebras. We have the exact sequence

$$0 \to \mathfrak{t}^k \to \mathfrak{t}^n \to \mathfrak{t}^d \to 0$$

and dualizing,

$$0 \to (\mathfrak{t}^d)^* \to (\mathfrak{t}^n)^* \to (\mathfrak{t}^k)^* \to 0.$$

We will often identify elements of $\mathfrak{t}^k$ with their images in $\mathfrak{t}^n$. Taking $\mu_k = \iota^* \circ \mu_n$ we obtain a moment map for the $T^k$ action on $T^*\mathbb{C}^n$. Fix a character $\theta$ of $T^k$ and a level $\xi \in (\mathfrak{t}^k)^*$. We define the associated **hypertoric variety** by

$$\mathcal{M}_{\theta, \xi} = \mu_k^{-1}(\xi)/\theta T^k,$$

where we take the GIT quotient with respect to the linearization determined by $\theta$.

The induced $T^d$ action on $\mathcal{M}_{\theta, \xi}$ preserves the holomorphic symplectic form. There is a further action of $\mathbb{C}^*$ dilating the fibers of $T^*\mathbb{C}^n$, which scales the symplectic form by $h$. This also preserves $\mu_k^{-1}(0)$, and visibly descends to an action of $\mathbb{C}^*$ on $\mathcal{M}_{\theta,0}$ commuting with the $T^d$ action. In the notation of (2.1.1), $G = T^d$ and $\mathcal{G} = T^d \times \mathbb{C}^*$.

### 3.1.2 Hyperplane arrangements

The geometry of hypertoric varieties can be described by means of a hyperplane arrangement. The Lie algebras $\mathfrak{t}^k, \mathfrak{t}^n$ and $\mathfrak{t}^d$ inherit integral structures from the associated tori. Let $(\mathfrak{t}^k)_\mathbb{R}^* = (\mathfrak{t}^k)^*_\mathbb{R} \otimes \mathbb{R}$, and define $(\mathfrak{t}^n)_\mathbb{R}^*$ and $(\mathfrak{t}^d)_\mathbb{R}^*$ analogously.

Choose a lift $\hat{\theta}$ of $\theta$ to $(\mathfrak{t}^n)^*$, with coordinates $\hat{\theta}_i$. Write $e_i$ for the standard
generators of \((t^n)_\mathbb{Z}\) and \(a_i\) for their images in \((t^d)_\mathbb{Z}\). Define hyperplanes \(H_1, ..., H_n\) in \((t^d)_\mathbb{R}\) by
\[
H_i = \left\{ x \in (t^d)_\mathbb{R}^*: a_i \cdot x + \hat{\theta}_i = 0 \right\}.
\] (3.1)
These are the intersections of \((t^d)_\mathbb{R}^* + \hat{\theta}\) with the coordinate hyperplanes of \((t^n)_\mathbb{R}^*\).

We call the collection of oriented affine hyperplanes \(\mathcal{A} = \{H_i\}_{i=1}^n\) the hyperplane arrangement associated to the hypertoric variety \(\mathcal{M}_{\theta,0}\). Each hyperplane \(H_i\) divides \((t^d)^*\) into a positive and a negative half space:
\[
x \in \begin{cases} 
\mathbb{H}_i^+ & \text{if } a_i \cdot x + \hat{\theta}_i \geq 0, \\
\mathbb{H}_i^- & \text{if } a_i \cdot x + \hat{\theta}_i \leq 0.
\end{cases}
\]

The arrangement \(\mathcal{A}\) is called
\begin{itemize}
  \item \textbf{Simple} if every subset of \(m\) hyperplanes with nonempty intersection intersects in codimension \(m\);
  \item \textbf{Unimodular} if any collection of \(d\) independent vectors in \(\{a_1, ..., a_n\}\) spans \(t^d\) over \(\mathbb{Z}\);
  \item \textbf{Smooth} if it is simple and unimodular.
\end{itemize}

The associated hypertoric variety is smooth if and only if the arrangement is smooth.
The affinization map is the canonical GIT map \(\mathcal{M}_{\theta,0} \to \mathcal{M}_{0,0}\), and it is birational. In particular, smooth hypertoric varieties are symplectic resolutions. \textit{We assume from now on that \(\mathcal{M}_{\theta,0}\) is smooth.} To reduce clutter, in the sequel we fix \(\theta\) and write \(\mathcal{M}\) for \(\mathcal{M}_{\theta,0}\).

\textbf{Example 3.1.1.} The hypertoric variety \(T^*\mathbb{P}^n\) is obtained as the quotient of \(T^*\mathbb{C}^{n+1}\) by the action of the diagonal torus. The corresponding hyperplane arrangement is composed of \(n + 1\) hyperplanes bounding a simplex in \(\mathbb{R}^n\). Dividing instead by the
complementary torus \{((\zeta_1, ..., \zeta_{n+1}) \in (\mathbb{C}^*)^{n+1} | \prod \zeta_i = 1}\} we obtain the \tilde{\mathcal{A}}_n surface, a crepant resolution of a type A_n singularity. The corresponding arrangement is simply \(n + 1\) points on a line.

**Example 3.1.2.** The following example is related to the abelianization of \(\text{Hilb}_2\), the Hilbert scheme of two points on \(\mathbb{C}^2\); the latter is isomorphic to \(T^* \mathbb{P}^1 \times \mathbb{C}^2\), but the quotient structure is different than the description in the previous example.

Let \(n = 4, k = d = 2\), with \(t^k\) spanned by \{(1, -1, 1, 0), (-1, 1, 0, 1)\}. Let \(\theta = (1, 1), \hat{\theta} = (0, 0, 1, 1)\). We choose the basis \(b_{12} = (1, 0, -1, 1), b_{21} = (0, 1, 1, -1)\) for \((t^d)^*\) (this notation is compatible with the treatment in chapter 6). The corresponding arrangement is given by the coordinate axes and the lines \(b_{21} = b_{12} \pm 1\). In the figure, arrows point towards the positive half planes. The shaded region is a cone in the arrangement, see (3.2.2) below.

\[\text{3.1.3 Cohomology}\]

Consider the character of \(T^n\) given by \(\text{diag}(\zeta_1, ..., \zeta_n) \mapsto \zeta_i\). Restricting to \(T^k\), we obtain an induced \(T^d \times \mathbb{C}^*\)-equivariant line bundle on \(\mathcal{M}\), with equivariant Euler class \(u_i\), corresponding to the divisor \(z_i = 0\). Recall that \(h\) is the weight of the symplectic form under the \(\mathbb{C}^*\) action; the divisor \(w_i = 0\) thus corresponds to the class \(h - u_i\).
Notation 3.1.3. For $S \subseteq \{1..n\}$, let $H_S = \cap_{i \in S} H_i$.

Definition 3.1.4. A circuit $S \subseteq \mathcal{A}$ is a minimal subset satisfying $H_S = \emptyset$. The orientation defines a splitting $S = S^+ \sqcup S^-$, where $i \in S^\pm$ if $H_{S \setminus \{i\}}$ lies in $\mathbb{H}_i^\pm$ respectively. Alternatively, $S$ corresponds to a minimal relation in $t^d$:

$$\sum_{i \in S^+} a_i - \sum_{i \in S^-} a_i = 0.$$ 

Theorem 3.1.5 ([14]). $H_{T^d \times \mathbb{C}}^\bullet(\mathcal{M})$ is generated by $u_1, \ldots, u_n, h$, subject to the relations

$$\prod_{i \in S^+} u_i \prod_{i \in S^-} (h - u_i)$$

(3.2)

for all circuits $S$. $H_h^\bullet(\mathcal{M})$ is obtained by imposing in addition all the linear relations

$$\sum c_i u_i \in \ker \iota^*.$$  

(3.3)

Notation 3.1.6. We will frequently encounter products such as those above, and it will be convenient to introduce the following formal “star notation”:

$$x^{s(i)} = \begin{cases} 
x & \text{if } s > 0 \\
h - x & \text{if } s < 0 \\
1 & \text{if } s = 0 \end{cases}$$

For example, given a circuit $S$, define the sign vector $(s_1, \ldots, s_n)$ by $s_i = \pm 1$ if $i \in S^\pm$, $s_i = 0$ if $i \notin S$. Then (3.2) is succinctly expressed as $\prod u_i^{s(i)}$. 

20
3.2 The stable basis from the arrangement

3.2.1 Arrangement constructions

Toric lagrangians

While we do not follow any particular reference in this section, much of the material is contained in [3]. To avoid trivialities, it will be convenient to assume the following irreducibility condition:

\[ a_i \notin t^k \text{ for any } i. \]

If \( a_i \in t^k \), then \( \mathcal{M} \) is the product of \( T^*\mathbb{C} \) with a smaller hypertoric variety. The arguments below are easily modified to accommodate this case.

**Definition 3.2.1.** Given \( U \subseteq \{1..n\} \), define the corresponding chamber in the arrangement as the intersection

\[ \bigcap_{i \in U} \mathbb{H}_i^+ \cap \bigcap_{i \notin U} \mathbb{H}_i^- \]

If the chamber is non-empty, there is a corresponding toric lagrangian subvariety of \( \mathcal{M} \) defined as follows. Let

\[ E_U^+ = \{ (z, w) \in T^*t^a \mid z_i = 0 \quad \forall i \in U \} \quad (3.4) \]

\[ E_U^- = \{ (z, w) \in T^*t^a \mid w_i = 0 \quad \forall i \in U \} \quad (3.5) \]

and set

\[ L_U = (\mu^{-1}(\lambda) \cap (E_U^+ \cap E_{A \setminus U}^-))//T^k. \]

The image of \( L_U \) under the moment map \( \mathcal{M} \to (t^d)^* \) is precisely the corresponding chamber in the arrangement [29]. Note that the smoothness conditions on the arrangement imply that \( L_U \) is a smooth toric variety. It is clear that all \( T^d \) invariant
lagrangians are obtained in this way. We define the core $C \subset M$ as the union of all $L_U \subset M$. Note that this is the image of $\mu_n^{-1}(0) = \{(z_i, w_i) : z_i = 0 \text{ or } w_i = 0 \quad \forall i\}$.

The core is a $T^d$-equivariant deformation retraction of $M$ [14, 29]. Using the restriction formulas below, one easily checks:

$$[C] = h^d[M].$$

**Example 3.2.2.** The figure illustrates the hyperplane arrangement for $T^*\mathbb{P}^2$. $L_{123}$ is the zero section, and its image under the moment map is the central simplex, while $L_1$ is the fiber over $[1:0:0] \in \mathbb{P}^2$, corresponding to the cone above the topmost vertex.

Hypertoric subvarieties

Given $Q = \{i_1, ..., i_r\} \subset \{1..n\}$, there is a hypertoric subvariety $M_Q \subset M$ whose hyperplane arrangement is given by the intersection of the ambient arrangement with $H_Q$. It is defined by

$$M_Q = (\mu^{-1}(\lambda) \cap E_Q^{+} \cap E_Q^{-})//_\theta T^k.$$  

Let $T^Q \leq T^d$ be the subtorus such whose Lie algebra $t^Q$ is generated by $\{a_{i_1}, ..., a_{i_r}\}$. Note that $T^Q$ fixes $M_Q$, and that $\dim T^Q = r$ by the smoothness condition on the arrangement. We denote by $\{\alpha_{i_1}, ..., \alpha_{i_r}\}$ the dual basis on $(t^Q)^*$. More generally, let $A \leq T^d$ be any subtorus. The connected components of $M^A$
are the subvarieties $M_Q$ above for minimal subsets $Q$ such that $A \leq T^Q$. In particular, if $A = T^d$, $M^A$ is discrete, and the fixed points correspond to the intersection of $d$ hyperplanes in the arrangement.

### 3.2.2 Stable leaves and stable envelopes

#### Stable leaves

Consider a subvariety $M_Q$ as above and a chamber in the arrangement $H_Q$ defined by $U^0 \subseteq A \setminus Q$, and corresponding to a Lagrangian $L^Q_{U^0} \subseteq M_Q$. Let $\sigma \leq T^Q$ be a generic cocharacter, and let

$$U^+ = \{j \in Q, (\alpha_j, \sigma) > 0\}.$$ 

Then $U^0 \cup U^+$ defines a chamber in the ambient arrangement $A$, and it is clear that $\sigma$ attains its minimum on this chamber precisely on the face defined by $Q$. It is easy to see from the definitions that the corresponding Lagrangian $L_{U^0 \cup U^+}$ is the stable leaf of $L^Q_{U^0}$. Since any $T^d$ invariant cycle is obtained in this way, we see that

**Proposition 3.2.3.** The closure of the stable leaf of any irreducible $T^d$ invariant cycle in $M$ is smooth.

This property makes the stable basis particularly simple in the hypertoric case: expressed in the stable leaf basis, all nonzero coefficients must be $\pm 1$.

#### Stable envelopes

With the same notation, define the *cone* of $L^Q_{U^0}$ as the union of all chambers in the intersection

$$(\cap_{j \in U^+} \mathbb{H}^+_j) \cap (\cap_{j \in Q \setminus U^+} \mathbb{H}^-_j),$$

(3.8)
see (3.1.2) for an example. The corresponding lagrangian in \( \mathcal{M} \) is a union of leaves, which is ordered by the minimal value attained by \( \sigma \) on each chamber. This order agrees with the partial order on stable leaves (cf. [3], 2.6). It is easy to see by induction that the lagrangian corresponding to the cone is contained in the slope of \( \mathcal{M}_Q \); in fact, up to sign this is precisely its stable envelope, as we will see below.

**Example 3.2.4.** Let \( X = T^*\mathbb{P}^n \) with the action by \((\mathbb{C}^*)^n\). The fixed points are indexed by \( \{0, ..., n\} \), where the fixed point \( i \) corresponds to the intersection \( H_{\mathcal{A}\setminus\{i\}} \) in the arrangement. Choosing \( \sigma \) to induce the natural order on the fixed points, we have an inclusion

\[
pt \subseteq \mathbb{P}^1 \subseteq \mathbb{P}^2 \subseteq ... \subseteq \mathbb{P}^n
\]

and the closure of the stable leaves are the conormal bundles \( N^*\mathbb{P}^i \). It is clear from the arrangement (see e.g. 3.2.2 for \( n = 2 \)) that the cone of the chamber corresponding to the leaf \( m_i \) is the union of \( m_i, m_{i-1} \), so as a cycle

\[
\text{stab}_i = N^*\mathbb{P}^i + N^*\mathbb{P}^{i-1}.
\]

**Remark 3.2.5.** In [4], the authors introduce an analogue of the BGG category \( \mathcal{O} \) for hypertoric varieties. The irreducible modules in this category are supported on the lagrangians corresponding to chambers of the arrangement, and the standard modules are supported on the cones, each chamber with multiplicity 1. This is another example of the correspondence between stable envelopes and standard modules in a suitable highest weight category (cf. 2.2.3).
3.3 The stable basis in terms of tautological classes

3.3.1 Restriction of tautological classes to fixed points

Let \( p \in \mathcal{M}^{T^d \times \mathbb{C}^*} \) be a fixed point corresponding to a d-tuple of hyperplanes indexed by \( V \subset \mathcal{A} \) and intersecting at a point \( H_V \). The action of \( T^d \times \mathbb{C}^* \) on \( T_p \mathcal{M} \) is described as follows [13]. Since we assume \( \mathcal{M} \) is smooth, the normals \( \{a_j\}_{j \in V} \) form a basis for \( t^d \). Let \( \alpha_j \) be the dual basis. Define \( \mathcal{A}_V^+ \subset \mathcal{A} \) by

\[
\mathcal{A}_V^+ = \{ H_i : H_V \not\in H_i, H_V \in \mathbb{H}_i^+ \}.
\]

It is easy to check from the moment map conditions that [13, 14]:

\[
\begin{cases}
  z_i = w_i = 0 & \text{if } i \in V \\
  z_i \neq 0, w_i = 0 & \text{if } i \in \mathcal{A}_V^+ \\
  z_i = 0, w_i \neq 0 & \text{if } i \in \mathcal{A}_V^-
\end{cases}
\]  \( (3.9) \)

The tangent space at \( p \) splits into a sum of \( T^d \times \mathbb{C}^* \)-stable lines corresponding to the \( 2d \) edges extending from \( H_V \). Given an edge \( e \), there is a single \( H_i \in V \) not containing \( e \). The associated weight is

\[
\begin{cases}
  \alpha_i - (\alpha_i, \sum_{j \in \mathcal{A}_V^+} a_j) h & \text{if } e \text{ extends into } \mathbb{H}_i^+; \\
  h - (\alpha_i - (\alpha_i, \sum_{j \in \mathcal{A}_V^-} a_j) h) & \text{if } e \text{ extends into } \mathbb{H}_i^-.
\end{cases}
\]

More generally, the normal weights to a hypertoric subvariety \( \mathcal{M}_Q \) are given by the same formula restricted to \( t^Q \) weights. It is an easy exercise to check that this is well defined.

Example 3.3.1. Consider the arrangement in (3.1.2), and let \( V = \{2, 4\} \). In the notation of (3.1.2), we have \( \alpha_2 = b_{12} + b_{21}, \alpha_4 = b_{12}, \) and \( \mathcal{A}_V^- = \{1\} \). The associated
weights are indicated in the figure; note that the weights of opposite edges always add to $h$.

The restriction of the tautological class $u_i$ to $p_V$ is given by:

**Proposition 3.3.2** ([13],3.5).

\[
u_{i\mid p_V} = \begin{cases} 0 & \text{if } i \in A_V^+ \\ h & \text{if } i \in A_V^- \\ \alpha_i - \left( \alpha_i, \sum_{j \in A_V^-} a_j \right) h & \text{if } i \in V. \end{cases}
\]

(3.10)

**Observation 3.3.3.** Note that if $\mathcal{M}_Q$ is a hypertoric subvariety, and the hyperplane $H_i$ is transverse to $H_Q$, then from the definitions, $u_{i\mid \mathcal{M}_Q} = u_i \in H^*_h(\mathcal{M}_Q)$. We will not distinguish in the notation between $u_i$ as a tautological class in $\mathcal{M}$ and $\mathcal{M}_Q$.

**Remark 3.3.4.** We will need the following observation. Let $L \subseteq \mathcal{M}_Q$ be a $\mathbb{C}^*_k$-invariant (but not necessarily $T^d$-invariant) cycle, such that the $L \cap \mathcal{M}_Q^*$ is discrete, and let $x \in L^\times$. Then $u_{i\mid x} \in H^*_{T^Q \times \mathbb{C}^*}(L)$ is given by the same formula (3.10) after restricting to $T^Q$ weights. The same proof as in [13], which explicitly computes the weights along the fiber over $T^d$ fixed points, works for this case as well.
3.3.2 The stable basis in terms of tautological classes

Given \( Q \subset A \), consider the hypertoric subvariety \( \mathcal{M}_Q \subset \mathcal{M} \), and let \( \mathcal{C}_Q \subset \mathcal{M}_Q \) be its core. Let \( T_Q \subset T^d \) be generated by \( a_i \) for \( i \in Q \); recall that \( T_Q \) fixes \( \mathcal{M}_Q \). Choose a chamber \( \mathcal{C} \subset t_Q = \text{Lie}(T_Q) \), and put \( Q^+_\mathcal{C} = \{ i : (\alpha_i, v) > 0 \text{ for } v \in \mathcal{C} \} \). Then by (3.3.2)

\[
\left( \prod_{i \in Q^+_\mathcal{C}} u_i \prod_{i \notin Q^+_\mathcal{C}} (\hbar - u_i) \right)_{\mathcal{M}_Q}
\]

is a polarization of the normal bundle of \( \mathcal{M}_Q \) with respect to the torus \( T_Q \times \mathbb{C}^* \). Denote it \( \epsilon_{\mathcal{C}} \).

**Theorem 3.3.5.** Let \( \gamma \in H^*_\hbar(\mathcal{M}_Q) \) be given by a polynomial \( p_\gamma \) in the tautological classes of \( \mathcal{M}_Q \). Then for the chamber \( \mathcal{C} \) and polarization \( \epsilon_{\mathcal{C}} \),

\[
\text{stab}_\mathcal{M}(\gamma) = p_\gamma \cdot \prod_{i \in Q^+_\mathcal{C}} u_i \prod_{i \notin Q^+_\mathcal{C}} (\hbar - u_i).
\]

**Proof.** First note that this expression is well defined: if \( p_\gamma = 0 \) in \( H^*_\hbar(\mathcal{M}_Q) \), then either it contains a circuit in \( \mathcal{M}_Q \), in which case (3.12) contains a circuit in \( \mathcal{M} \); or \( p_\gamma \) contains a linear relation as in (3.3), but these vanish in the restriction from \( T^d \) to \( T^Q \) weights.

From the definition of the stable basis and (3.3.3), it is enough to prove the case \( \gamma = 1 \). Moreover, since the core \( \mathcal{C}^Q \) is a deformation retraction of \( \mathcal{M}^Q \) and \( \mathcal{C}^Q \subseteq \mathcal{C} \), we may work on the core and assume \( \gamma = |\mathcal{C}^Q| = \hbar^{d-|Q|} \) (3.6). Since \( T^Q \)-equivariant tautological classes lift naturally to \( T^d \) equivariant classes, we can work in \( T^d \) equivariant cohomology and restrict to \( T^Q \) equivariant parameters. Then from the description of the slope in (3.2.2) and the restriction rules (3.10), we see that (3.12) is supported on the slope. The divisibility condition in (2.2.2) again follows from (3.10), while the normalization condition is clear. 

\( \square \)
Chapter 4

Abelianization of Stable Envelopes

In this chapter we prove our main theorem (4.3.1), relating stable envelopes in abelian and non-abelian hyperkähler quotients. We also obtain the restriction formula (4.3.3) of stable envelopes to fixed points. Though many of the results hold in greater generality, it will be convenient to assume that our quotients are quiver varieties.

4.1 Abelianization of hyperkähler quotients

4.1.1 Hyperkähler quotients from the GIT point of view

We adopt here the GIT point of view for hyperkähler quotients. The interplay between the various abelian and non-abelian quotients plays an important role in what follows; we review the definitions and notation for the reader’s convenience.

Let $V$ be a complex vector space, $X = T^*V$ with the canonical symplectic form $\omega$. Let $G$ be a complex reductive group acting on $V$, and $T \leq G$ a maximal torus. The $G$ action on $V$ induces a canonical hamiltonian action on $X$; let $\mu_G : X \to g^*$ be the moment map. Composing with the projection $pr : g^* \to t^*$, we obtain a moment map $\mu_T = pr \circ \mu_G$ for the $T$ action on $X$. Let $\xi \in Z(g^*)$, i.e. $\xi$ is a fixed point of the
coadjoint action. We may also think of $\xi$ as an element of $\mathfrak{t}^*$. We denote

$$X^\xi_G = \mu^{-1}_G(\xi) \quad X^\xi_T = \mu^{-1}_T(\xi).$$

There are closed inclusions

$$X^\xi_G \subseteq X^\xi_T \subseteq X.$$

We use similar notation for other subgroups of $G$. When $\xi = 0$ we put $X_G = X^0_G$, and similarly for $T$.

Fix a generic character $\theta$ of $G$ once and for all. For a variety $Y$ on which $G$ acts, we call a point $y \in Y$ $G$-semistable if it is $(\theta, G)$-semistable in the GIT sense, and denote the $G$-semistable locus of $Y$ by $Y^{G-ss}$. Viewing $\theta$ as a character of $T$, we define $T$-semistability similarly; there are open inclusions

$$Y^{G-ss} \subseteq Y^{T-ss} \subseteq Y.$$

We denote the GIT quotient of the $G$, resp. $T$-semistable loci by $//G$, $//T$, e.g.:

$$Y//\theta G = Y^{G-ss}/G \quad Y//\theta T = Y^{G-ss}/T.$$

Letting now $Y = X^\xi_G$ or $Y = X^\xi_T$, we obtain the hyperkähler quotient by $G$ and the corresponding abelian quotient:

$$X^\xi//G := X^\xi_G//\theta G \quad X^\xi//T := X^\xi_T//\theta T,$$

as well as the intermediate quotients $X^\xi_G//\theta T, X^\xi_G//\theta T$. These play a central role in what follows and we denote

$$X^\xi//\theta := X^\xi_G//\theta T.$$

When $\xi = 0$, we again suppress it from the notation.
Remark 4.1.1. For generic values of $\xi$, which are regular values for $\mu_G, \mu_T$ on all of $X$, the quotients $X^{\xi}/G, X^{\xi}/T, X^{\xi}/T \cap G$ are smooth and affine. In this setting, the family $X^{\xi}/G, t \in \mathbb{C}$ is a deformation of $X/G$ over $\mathbb{C}$ as in (2.2.3), and similarly for the various other quotients introduced here. All the constructions presented below for $\xi = 0$ extend equivariantly to the families obtained by varying $\xi$.

Remark 4.1.2. These constructions and all other results presented in this section extend with obvious modifications when $T$ is replaced by any maximal rank reductive group. These will be important for us later, but for ease of presentation we only use the $T$ quotient here.

Example 4.1.3. Let $X/G = T^*Gr(k,n)$ be the cotangent bundle to the Grassmannian, obtained as the Nakajima quiver variety of type $A_1$. Then $X/T \cong T^*(\mathbb{P}^{n-1})^k$ (see 5.1.2). More generally, replacing $T$ with a reductive group $L \cong \prod GL(k_i), \sum k_i = n$, we have $X/L = \prod T^*Gr(k_i,n)$.

4.1.2 Smoothness

We are interested in the case where $X/G$ is a symplectic resolution, in particular, it is smooth. We therefore assume:

1. $0$ is a regular value for the $\mu_G, \mu_T$ actions restricted to the semistable loci;

2. $\theta$ is generic for both the $G$ and $T$ actions.

The latter condition means that all semistable points are actually stable, and that the $G, T$ actions on the respective stable loci is locally free.

Proposition 4.1.4. If $X/G$ is a Nakajima quiver variety satisfying the above conditions, then $X/T$ is smooth (in particular, a symplectic resolution).

Proof. We need to show that $T$ stabilizers are trivial on $T$-stable points which are not $G$-stable. Let $x$ be such a point; then the stabilizer $G_x$ is connected ([10], 1.3.2). Since $G$ is of type $A$, $G_x \cap T$ is connected. Being finite, it is trivial. \qed
4.1.3 The Martin Diagram

The various quotients we have introduced are related by the following diagram due to Martin (cf. [21, 15, 7]):

\[
\begin{array}{ccc}
X/\!/\!\!\!\!\!\!/G & \xrightarrow{j} & X/\!/\!\!\!\!\!\!/T \\
\downarrow\pi & & \downarrow\pi \\
X/\!/\!\!\!\!\!\!/T & \rightarrow & X/\!/\!\!\!\!\!\!/G \\
\end{array}
\]

(4.1)

Here, \( i \) is a closed inclusion and \( j \) is an open embedding; we put \( \iota = i \circ j \). \( \pi \) is a flat bundle with affine fiber \( G/T \). We call its fibers the \textit{vertical} fibers. The symplectic forms \( \omega_G, \omega_T \) of \( X/\!/\!\!\!\!\!\!/G \hookrightarrow X/\!/\!\!\!\!\!\!/T \) are \textit{compatible} in the sense that

\[
\iota^* \omega_T = \pi^* \omega_G.
\]

In particular, the vertical fibers are isotropic; in other words, \( \omega_T \) matches the vertical directions with the normal bundle to \( X/\!/\!\!\!\!\!\!/G \) in \( X/\!/\!\!\!\!\!\!/T \).

Note that since the Weyl group \( W = W(G, T) \) normalizes \( T \), it acts on all the abelian quotients.

\textbf{Remark 4.1.5.} Let \( x \in X/\!/\!\!\!\!\!\!/G \). Then locally at \( x \),

\[
X/\!/\!\!\!\!\!\!/T \cong X/\!/\!\!\!\!\!\!/G \times T^*G/T.
\]

This follows from a general fact about the local structure of symplectic quotients ([12], §41). We will only be using this description to highlight the geometry, and therefore favor this abuse of notation in the interest of clarity.

\textbf{Remark 4.1.6.} Hyperkähler quotients may also be described as symplectic quotients by a compact Lie group. The quotients \( X/\!/\!\!\!\!\!\!/G, X/\!/\!\!\!\!\!\!/T \) remain the same when described
as the quotients by maximal compact subgroups of $G,T$ respectively. This is not true for intermediate quotients: the quotient denoted by $\mu^{-1}_G(0)/T$ in [15] corresponds to what we denote below by $\mu^{-1}_G(0)/B$. Their inclusion $\mu^{-1}_G(0)/T \hookrightarrow X//T$ is not algebraic, as it requires the $C^\infty$ isomorphism $G/T \cong T^*G/B$.

4.1.4 Cohomology

Line bundles

Let $\Delta$ be the root system of $G$. For a character $\alpha$ of $T$ and the corresponding 1-dimensional representation $C_\alpha$, there is an induced line bundle over $X//T$,

$$\mathcal{L}_\alpha = X_T \times \mathbb{C}_\alpha.$$  

We denote its Euler class by $e_\alpha$.

Following Martin [21], we observe that restricting $\mu_G$ to $X_T$ defines a $T$-equivariant map to $\ker(pr : g^* \rightarrow t^*)$, which descends to an equivariant section $s$ of the bundle $\bigoplus_{\alpha \in \Delta} \mathcal{L}_\alpha$. The assumption that 0 is a regular value of $\mu_G$ implies that this section is generic. The zero set of $s$ is $X_\alpha//_T T$, therefore the Euler class of its normal bundle in $X//T$ is

$$Eu(X_\alpha//_T T) = Eu\left(\bigoplus_{\alpha \in \Delta} \mathcal{L}_\alpha\right) = \prod_{\alpha \in \Delta} e_\alpha.$$  \hspace{1cm} (4.2)

Note again that these constructions extend to the family obtained by varying $\xi$.

Torus action

Assume now that $X = T^*V$ admits an algebraic action by an additional complex torus $A$, satisfying the following conditions:

1. The $A$ action and the $G$ action commute.

2. $A$ scales the symplectic form by a non-trivial character $\mathring{\kappa}$.
3. The moment map $\mu_G$ is $A$-equivariant, where $A$ acts on $g^*$ by scaling by $h$.

These assumptions hold, for example, for the framing action in Nakajima varieties. Note that the first assumption implies that the semistable loci are $A$-stable, and therefore the $A$ action descends to the quotients. The third assumption implies that the bundles $L_\alpha$ are $A$-equivariant. We denote by $A_0 \leq A$ the stabilizer of $\omega_G$, and by $H^*_h$ equivariant cohomology with respect to $A/A_0$.

**Abelianization**

By an equivariant version of a standard theorem of Borel, $\pi^*$ is an isomorphism onto the $W$-invariant part of $H_A^*(X/\mathcal{U})$. Then we have:

**Theorem 4.1.7** ([15]). The map

$$\Theta^G_T = (\pi^*)^{-1} \circ \iota^* : H_A^*(X/\mathcal{T})^W \to H_A^*(X/\mathcal{G})$$

is surjective and its kernel is the annihilator of

$$e = \prod_{\alpha \in \Delta} e_{\alpha}(h - e_{\alpha}) \in H_A^*(X/\mathcal{T})^W.$$ 

In particular, classes supported on the $G$-unstable locus kill $e$.

**Lifts** [21, 7]

There are Kirwan maps:

$$\kappa_G : H^*_{A \times G}X \to H_A^*(X/\mathcal{G}) \quad \kappa_T : H^*_{A \times T}X \to H_A^*(X/\mathcal{T})$$
which we assume to be surjective; this holds in the quiver case after inverting \( A \) weights [15]. We also have the standard restriction map

\[
r^G_T : H^*_{A \times G}(X) \to H^*_{A \times T}(X)^W.
\]

We call a class \( \dot{\gamma} \in H^*_A(X//T) \) a lift of \( \gamma \in H^*_A(X//G) \) if there exists \( \bar{\gamma} \) such that

\[
\gamma = \kappa_G(\bar{\gamma}) \quad \quad \quad \dot{\gamma} = \kappa_T \circ r^G_T(\bar{\gamma})
\]

We can choose \( \dot{\gamma} \) to be \( W \) invariant. In this case \( \Theta^G_T(\dot{\gamma}) = \gamma \), i.e.

\[
t^*(\dot{\gamma}) = \pi^*(\gamma).
\]

Thinking of \( \gamma \) as a cycle, in the local description (4.1.5) we have \( \dot{\gamma} \cong \gamma \times T^*G/T \).

### 4.2 Fixed components

#### 4.2.1 Fixed components and abelianization

**Lifts of fixed components**

Let \( \dot{Z} \in F_{A_0}(X//T) \), \( x \in \dot{Z} \). The fiber over \( x \) in \( X^{T-ss} \) is an \( A_0 \)-stable \( T \)-orbit on which \( T \) acts freely. Since the \( A_0 \) and \( T \) actions commute, we obtain a map \( \Phi_{\dot{Z}} : A_0 \to T \) defined by

\[
ay = \Phi_{\dot{Z}}(a)y
\]

for any point \( y \) in this orbit. By continuity, \( \Phi_{\dot{Z}} \) is independent of \( x \). We put

\[
\alpha(\dot{Z}) := \Phi^*_Z(\alpha),
\]
where $\Phi_Z^*: t^* \to a^*$ is the induced map. Since $A$ acts on $g^*$ with weight $h$, we see that

$$e_\alpha|_Z = h + \alpha(\dot{Z}) \in H_\lambda(pt). \quad (4.5)$$

Now let $Z \in F_{A_0}(X//G), x \in Z,$ and consider the $A_0$ action on the fiber in $X^{G-ss}$ over $x$. Indetifying

$$\pi^{-1}(x) \cong G/T$$

and for $y \in G/T$, we obtain maps $\Phi_{Z,y}: A_0 \to G$ using the same definition 4.4, and the dependence on $y$ is $G$-equivariant. It is clear that $y \in (X//T)^{A_0}$ iff the image of $\Phi_{Z,y}(A_0)$ lands in $T$, and that all the $W$-conjugates of $y$ are also fixed. In this case,

**Observation 4.2.1.** The vertical directions at $y$ on which $A_0$ acts with weight 0 are identified with the roots contained in the centralizer $G_Z$ of $A_0$.

Let $W_Z, \Delta_Z$ be the Weyl group and root system of $G_Z$ respectively. These are well defined up to conjugation, and we conclude:

**Proposition 4.2.2.**

$$(X//T)^{A_0} \cap \pi^{-1}(x) \cong G_Z/T \times W/W_Z \quad (4.6)$$

We call any component $\dot{Z} \in F_{A_0}(X//T)$ intersecting $\pi^{-1}(x)$ a lift of $Z$; the terminology is justified by the lemma below. We see that $Z$ has exactly $|W/W_Z|$ lifts.

**Abelianization of fixed components**

Suppose $X//G$ is a quiver variety, and recall that we had $X = T^*V$. Choose a lift of $Z$ and let $V_Z \leq V$ be the subspace which the $A_0$ action coincides with the $\Phi_Z(A_0)$ action. It is shown in ([22], 2.3) that $Z$ is itself a quiver variety, obtained as

$$Z = T^*V_Z//G_Z. \quad (4.7)$$
Lemma 4.2.3. Let $\dot{Z}$ be a lift of $Z$. Then

$$\dot{Z} \cong T^*V_Z//T.$$ 

Proof. By choosing a conjugate of $\Phi_Z$ so that $A_0$ lands in $T$, it is clear that the $T$ orbits in $T^*V_Z$ are $A_0$-stable. In (4.7), the moment map and the stability conditions for $G_Z$ are obtained by restriction from $G$. Since $T \leq G_Z$, they agree with the ones in $X//T$. \qed

In particular, the lifts of any $\gamma \in H_b^*Z$ are defined as in (4.1.4). We refer the reader to (6.3.1) for interesting examples in the abelianization of $\text{Hilb}_n\mathbb{C}^2$.

4.2.2 Extended Martin Diagram

Fix a Borel subgroup $B \leq G$ containing $T$. Let $P$ be a parabolic subgroup containing $B$, $L \times U$ its Lévi decomposition. Recall the notation

$$\mu_P = (g^* \to p^*) \circ \mu, \quad X_p = \mu_P^{-1}(0).$$

We first note

Proposition 4.2.4. The geometric quotient of $X_G$ by $P$ exists.

Proof. The proof given in ([7], 2.5) for Borel subgroups also holds for parabolics. \qed
We have the following extended version of the diagram (4.1):

\[
\begin{array}{c}
X_{g//L} \xrightarrow{i_G} X_{P//L} \xrightarrow{i_P} X//L \\
\downarrow j_G \quad \downarrow j_P \quad \downarrow j_L \\
X_{g//L} \xrightarrow{\pi_P} X_{g//P} \xrightarrow{\pi_G} X//G
\end{array}
\]  \hspace{1cm} (4.8)

Here, the maps $j$ are open inclusions of the $G$-semistable in the $L$-semistable loci, and the maps $i, \iota$ are closed inclusions. Note that $i_G$ is a regular embedding, whereas $i_G$ need not be. $\pi_P$ is an affine bundle with fiber $U = P/L$, and $\pi_G$ is proper with fiber $G/P$. We abbreviate $X//P = X_{g//P}, X//G = X_{g//G}.$

From now on we consider the case where $L = G_Z$ for some $Z \in F_{A_0}(X//G)$ and $P$ is the unique parabolic containing $B$ whose Lévi factor is $L$. Let $j^A_G, \pi^A_G$ etc. be the restrictions of the maps in (4.8) to the $A_0$-fixed locus. Then using (4.7,4.2.1), we note that:

**Observation 4.2.5.**

1. The maps $j^A, i^A, \iota^A$ (with any subscript), and $\pi^A_P$ are isomorphisms;

2. The fibers of $\pi^A_G$ are discrete.

### 4.2.3 Dominant lifts

Let $\Delta = \Delta^+ \sqcup \Delta^-$ be the decomposition of $\Delta$ into positive and negative roots with respect to $B$. Fix a generic cocharacter $\sigma$ of $A_0$, $Z$ as above. The following is a key definition:
**Definition 4.2.6.** We say that a lift $\hat{Z} \in F_{A_0}(X//L)$ of $Z$ is dominant if $\sigma$ pairs positively with all the roots $\Delta^+ \setminus \Delta^+_Z$ under the induced map $\Phi_{\hat{Z}} : A_0 \to T$.

Clearly, $Z$ has precisely one dominant lift; its other lifts are obtained as its conjugates under $W/W_Z$. The following simple lemma characterizes the dominant lift, and is the geometric crux of the argument for proving the abelianization theorem. We retain the notation of the previous section; recall that $m$ denotes the stable leaf (2.2.1).

**Proposition 4.2.7.** The following are equivalent:

1. $\hat{Z}$ is the dominant lift of $Z$;

2. $\pi^{-1}_P(\pi^A_P(\hat{Z})) \subseteq m(X//_L, \hat{Z})$;

3. $m(X//P, \pi^A_P(\hat{Z}))$ is transverse to the fiber $\pi^{-1}_G(Z)$.

4. $m(X//L, \hat{Z}) \subseteq X//_L$;

**Proof.** The equivalence of the first three claims follows directly from the definition of a dominant lift by examining the weights of the $A_0$ action on the vertical directions. To see (4), note that it is enough to check the inclusion locally on the tangent space, since $X//_L$ is a closed $A_0$-stable subvariety. Similarly to 4.2, the Euler class of the normal bundle to $X//_L$ in $X//_L$ is

$$Eu(X//_L) = \prod_{\alpha \in \Delta^+ \setminus \Delta^+_Z} e_\alpha. \quad (4.9)$$

The weights of the $A_0$ action on the repelling vertical directions are given by $-\alpha(\hat{Z})$ for $\alpha \in \Delta^+ \setminus \Delta^+_Z$. The symplectic form must match them with the attractive normal weights $h + \alpha(\hat{Z})$, which are precisely those contained in $X//_L$. The claim follows.
4.3 Abelianization theorem

4.3.1 Main Theorem

Our goal in this section is to relate stable envelopes on $X\//G$ and $X\//T$. We will see that taking stable envelopes does not commute with abelianization; instead, we have to restrict to dominant lifts. We use $\sigma$ and the standard polarization induced from $X = T^*V$ to define stable envelopes with respect to the $A$ action. We retain the notation of the previous section, and denote stable envelopes in $X\//G$ by $\text{stab}_G$, and similarly for $T,L$.

Theorem 4.3.1. Let $Z \in F_{A_0}(X\//G)$, $\tilde{Z}, \check{Z}$ its dominant lifts to $X\//L, X\//T$ respectively. Let $\gamma \in H^*_h(Z)$, $\check{\gamma}, \tilde{\gamma}$ its lifts to $\check{Z}, \tilde{Z}$. Let

$$\Theta : H^*_A(X\//T)^W \to H^*_A(X\//L) \quad \Theta^A : H^*_h(\check{Z})^W \to H^*_h(\check{Z})$$

be as in (4.1.7), so that $\Theta^A(\check{\gamma}) = \tilde{\gamma}$. Then

1. $\text{stab}_T(\tilde{\gamma})$ is $W_L$-invariant and

$$\Theta(\text{stab}_T(\tilde{\gamma})) = \text{stab}_L(\gamma).$$  \hspace{1cm} (4.10)

2. There exist classes $s_P^{\text{hor}}(\tilde{\gamma}) \in H^*_A(X_P\//G_L)$, $s_P^{\text{ver}}(\tilde{\gamma}) \in H^*_A(X\//P)$ such that

$$j^*_L(\text{stab}_L(\check{\gamma})) = \iota_P(s_P^{\text{hor}}(\tilde{\gamma})) \hspace{1cm} (4.11)$$

$$\iota^*_G(s_P^{\text{hor}}(\tilde{\gamma})) = \pi_P(s_P^{\text{ver}}(\tilde{\gamma})) \hspace{1cm} (4.12)$$

$$\pi_G(\text{stab}_G(\gamma)) = \text{stab}_G(\gamma) \hspace{1cm} (4.13)$$

39
Remark 4.3.2. For an equivalent formulation of (2), construct the quotient \( X_{\mathbb{A}}/\mathbb{P} \).
Completing the diagram (4.8), we obtain correspondences

\[
X_{\mathbb{A}}/\mathbb{P} \rightarrow X/\mathbb{L} \quad \quad \quad X_{\mathbb{A}}/\mathbb{P} \rightarrow X/G.
\]

Then the theorem asserts that there exists a class in \( H^*_A(X_{\mathbb{A}}/\mathbb{P}) \) mapping to \( \text{stab}_L(\dot{\gamma}) \), \( \text{stab}_G(\gamma) \) respectively.

Proof. We prove both parts of the theorem together, first for \( \gamma = [Z] \). Recall from (2.3) that \( \text{stab}_G(Z) \) is obtained by specializing the stable leaves on a family of affine deformations. Since all the relevant operations commute with specialization ([8], 10.1), it is enough to prove the theorem on the affine fibers. Note in particular that since there are no unstable points in the affine fiber, when specializing the open inclusion \( j \), any corrections for leaves of fixed components supported in the \( G \)-unstable locus cannot involve leaves of \( G \)-stable components.

Fix a generic \( \xi \in g^* \) as in (4.1.1), and let \( Z^\xi \) be the fixed component specializing to \( Z \), and similarly for \( \tilde{Z} \). We denote the specialization to the central fiber by \( \lim_{\xi \to 0} \). Since \( X^\xi/G, X^\xi/\mathbb{L}, X^\xi/T \) are all affine and \( X^\xi/\mathbb{P} \) fibers over \( X^\xi/G \), the following are algebraic cycles (cf. 2.2.1):

\[
\begin{align*}
m_G &= m(X^\xi/G, Z) & m_L &= m(X^\xi/\mathbb{L}, \tilde{Z}) & m_T &= m(X^\xi/T, \tilde{Z}) \\
m_{\mathbb{L}} &= m(X^\xi/\mathbb{L}, \tilde{Z}) & m_{\mathbb{P}} &= m(X^\xi/\mathbb{P}, \pi^A_\mathbb{P}(\tilde{Z}))
\end{align*}
\]

Part (1) says that in the diagram (4.1) with \( G = \mathbb{L}, \pi^* m_L = \iota^* m_T \) which is obvious since \( \pi^{-1}(\tilde{Z}) \) is fixed by \( A_0 \). For part (2) we show:

1. \( m_L \subseteq X^\xi/\mathbb{L} \)
2. \( m_G = \pi^*_\mathbb{P}(m_{\mathbb{P}}) \)
3. \( m_G = (\pi_G)_*(m_{\mathbb{P}}) \)
This essentially follows from (4.2.7). The first claim is its part (4). For the second claim, since both sides are closed, irreducible, $A_0$-invariant cycles, it is enough to check the claim locally near $\dot{Z}$, where it follows from part (2). The last claim follows similarly from part (3). By the first claim, there is a class $m^{\text{hor}}_P$ pushing forward to $m_L$, and clearly $m_G = \iota_G^* m^{\text{hor}}_P$. The theorem follows readily by specializing to the central fiber, where we take

$$s_P^{\text{ver}} = \lim_{\xi \to 0} m_P^{\text{ver}}, \quad s_P^{\text{hor}} = \lim_{\xi \to 0} m_P^{\text{hor}}. \quad (4.14)$$

To show the theorem for general $\gamma \in H^*_b(Z)$, recall from (2.2.2) that the map $\text{stab}_L$ is given by a correspondence in $X//L \times (X//L)^{A_0}$, proper over $X//L$. It is clear that restricting to $X//L \times \dot{Z}$ computes $\text{stab}_L$ on $\dot{Z}$; we still call this correspondence $\text{stab}_L$, and similarly for $G, T$. Our argument above shows that the theorem holds for these correspondences, e.g.

$$(\Theta \otimes \Theta^A)(\text{stab}_T) = \text{stab}_L$$

$$(\pi_G \times \pi_G^A)_*(s_P^{\text{ver}}) = \text{stab}_G$$

We show the first part of the theorem (4.10). Denote projections to $X//T$, $X//L$, $X//T$ by $p_T, p_L, p_T^L$, projections to $\dot{Z}, \ddot{Z}, \pi^{-1}(\ddot{Z})$ by $p_Z$, and restrictions of maps in the diagram (4.1) to $\dot{Z}, \ddot{Z}$ by the subscript $Z$. Then using the property (4.3) of lifts, and since $\iota$ is a composition of an open inclusion with a regular embedding and $\pi$ is flat,

$$\pi^* \text{stab}_L(\gamma) = \pi^* p_L_*(\text{stab}_L \cap p_Z^* \gamma) = p_T^L_* ((\pi \times \pi_Z)^* (\text{stab}_L \cap p_Z^* \gamma)) =$$

$$p_T^L_* ((\iota \times \iota_Z)^* \text{stab}_T \cap p_Z^* \pi_Z^* \gamma) = p_T^L_* ((\iota \times \iota_Z)^* \text{stab}_T \cap p_Z^* \pi_Z^* \gamma) =$$

$$p_T^L_* (\iota \times \iota_Z)^* (\text{stab}_T \cap p_Z^* \gamma) = \iota^* p_T^* (\text{stab}_T \cap p_Z^* \gamma) = \iota^* \text{stab}_T(\gamma).$$

This implies that $\text{stab}_T$ is $W_L$-invariant since $\pi^*$ lands in the restriction of the $W_L$
invariant part. Note that the necessary properness condition for \( p_L \) hold ([8], 1.7).

For the second part the computation is similar, in fact simpler. We show, for example, (4.13), using analogous notation:

\[
\pi_G \ast (s^\text{ver}_P(\gamma)) = \pi_G \ast p \ast (s^\text{ver}_P \cap p^*_Z \gamma) = p_G \ast (\pi_G \times \pi_G^A) \ast (s^\text{ver}_P \cap p^*_Z \gamma) = p_G \ast ((\pi_G \times \pi_G^A) \ast (s^\text{ver}_P \cap p^*_Z \gamma)) = p_G \ast (\text{stab}_G \cap p^*_Z \gamma) = \text{stab}_G(\gamma).
\]

Here 1 follows from the fact that \( \pi_G^A \) is an isomorphism when restricted to any lift (4.2.5), and 2 is the projection formula. This concludes the proof of the theorem.

\[\Box\]

### 4.3.2 Restriction formula

We obtain a formula for the restriction of the stable basis to fixed points as follows.

**Corollary 4.3.3.** With the notation of (4.3.1) and \( Z' \in F_{A_0}(X//G) \), \( \tilde{Z}' \) any lift to \( X//T \),

\[
\text{stab}_G(\gamma)|_{Z'} = \sum_{w \in W/W_Z} \prod_{\alpha \in \Delta^- \setminus \Delta_Z} \frac{\text{stab}_T(\gamma)|_{w \cdot \tilde{Z}'}}{\alpha(w \cdot \tilde{Z}') \cdot (h + \alpha(w \cdot \tilde{Z}'))} \quad (4.15)
\]

The sum is to be understood as restricted to the support of \( \text{stab}_T(\gamma) \), i.e. terms where the numerator vanishes are discarded even if there are 0 weights in the denominator.

**Proof.** By part (1) of the theorem and (4.3),

\[
\text{stab}_T(\gamma)|_{w \cdot \tilde{Z}'} = \text{stab}_L(\gamma)|_{w \cdot \tilde{Z}'}.
\]

By (4.11), \( \text{Eu}(X_{v//_g L}) \) divides \( i_G^\ast(s^\text{hor}_P) \) in \( H_A^\ast(X//\gamma) \). Therefore, using (4.5,4.9), and
noting that $\alpha(\mathcal{Z}') = \alpha(\mathcal{Z}')$, we have:

$$\iota^*_G(s_{P}^{\text{hor}})|_{w \cdot \mathcal{Z}'} = \frac{\text{stab}_{\mathcal{G}}|_{w \cdot \mathcal{Z}'}(h + \alpha(w \cdot \mathcal{Z}'))}{\prod_{\alpha \in \Delta - \Delta_{\mathcal{Z}}} (h + \alpha(w \cdot \mathcal{Z}'))}.$$ 

Since $\pi_{P}$ is an affine bundle and by (4.12), the restriction $s_{P}^{\text{hor}}|_{\pi_{P}^{\Delta}(w \cdot \mathcal{Z}')}^{\Delta}$ is given by the same formula. Finally, to compute $\text{stab}_{\mathcal{G}} = \pi_{G}^{\Delta}(s_{P}^{\text{ver}})$, we may use the localization formula, since the fixed points along the fiber are isolated, and we have assumed formality. We obtain:

$$\text{stab}_{\mathcal{G}}|_{\mathcal{Z}'} = \sum_{w \in W_{\mathcal{Z}}} \frac{s_{P}^{\text{ver}}|_{\pi_{P}^{\Delta}(w \cdot \mathcal{Z}')}}{\prod_{\alpha \in \Delta - \Delta_{\mathcal{Z}}} \alpha(w \cdot \mathcal{Z}')}$$

the denominator being the product of weights along the fiber. The claim follows. 

**Remark 4.3.4.** To use this formula in practice for quiver varieties, one may proceed as follows. If $\gamma$ is given as a polynomial in Chern classes of tautological bundles, its lift can be computed explicitly by replacing each Chern class with an elementary symmetric polynomial in the Chern roots, which are tautological classes on $X/\Pi T$. Then we express $\text{stab}_{\mathcal{T}}(\check{\gamma})$ in tautological classes using (3.3.5).

Next, it may be more convenient to compute the restriction of $\text{stab}_{\mathcal{L}}(\check{\gamma})$ rather than $\text{stab}_{\mathcal{T}}(\check{\gamma})$. If the $h$ fixed points along the fiber of $\pi$ are isolated, then we may apply (3.3.4) at any of these points to obtain the result as an $A$ weight. We will use this method in chapter 6.
Chapter 5

Abelianization for Type A Partial Flag Varieties

Fix $k_1 < ... < k_r < k_{r+1} = n$, and let $\mathcal{F} = \mathcal{F}(k_1, ..., k_r, n)$ be the variety of partial flags $C^{k_1} \subseteq C^{k_2} \subseteq ... \subseteq C^{k_r} \subseteq C^n$.

The cotangent bundle $X_G = T^* \mathcal{F}$ is the Nakajima variety of a type $A_r$ quiver with the dimension vector $(k_i)_{i=1}^r$ and framing vector $(0, ..., 0, n)$. Recall that the stable envelope can be identified with the characteristic cycle of a Verma module (2.2.3). In this chapter we apply the abelianization formula to compute the restriction of the stable envelope to fixed points. When $r = 1$, i.e. $X_G = T^*Gr(k_1, n)$, the corresponding quantum integrable system is the $XXX$ spin chain, and we recover in a geometric way an explicit diagonalization of the Hamiltonian at $q = 0$. We also recover the fixed-point restriction of equivariant Schubert classes.

Notation 5.0.5. For the rest of this paper, we simplify the notation for hyperkähler quotients, and put $X_G = X//G, X_T = X//T$. 
5.1 Partial flag varieties and their abelianization

5.1.1 Hyperkähler construction

Let $G = \prod_{i=1}^{r} \text{GL}_{k_i}(\mathbb{C})$. The cotangent bundle $X_G = T^*\mathcal{G}$ is obtained as the hyperkähler quotient

$$T^* \bigoplus_{l=1}^{r} \text{Hom}(\mathbb{C}^{k_l}, \mathbb{C}^{k_{l+1}}) \backslash \! \! / G,$$

where $\text{GL}_{k_i}$ acts on the $l$-th factor on the left, and on the $l-1$-th factor on the right. For $A_l \in \text{Hom}(\mathbb{C}^{k_l}, \mathbb{C}^{k_{l+1}})$, $B_l \in (\mathbb{C}^{k_{l+1}}, \mathbb{C}^{k_l})$, $i \in \text{Hom}(\mathbb{C}^{k_r}, \mathbb{C}^n)$, $j \in \text{Hom}(\mathbb{C}^n, \mathbb{C}^{k_r})$, the moment map is given by (2.2)

$$\mu(A, B, i, j) = \sum_{l=1}^{r-1} [A_l, B_l] + ij$$

and we use the product of the determinants as the stability parameter. For the abelianization $X_T$ we use the product of diagonal tori $T = \prod_{i=1}^{r} T_{k_i}$, and the Weyl group is $W = \prod S_{k_i}$. It is easy to check the smoothness conditions (4.1.2) for $X_T$.

5.1.2 Description of the abelian quotient

The Grassmannian case

In the simplest case $r = 1$, i.e. $X_G = T^*\text{Gr}(k, n)$, the construction is particularly simple, and $X_T = (T^*\mathbb{P}^{n-1})^k$. Explicitly, for a map $S : \mathbb{C}^k \to \mathbb{C}^n$ and $Q$ in the fiber over $S$, the semistable points are those with $\text{rk}(S) = k$, and the moment map for the $G = \text{GL}(k)$ action is given by $\mu_G(S, Q) = Q \cdot S$. Thinking of $S$ as an element of $\text{Gr}$ and identifying the fiber over it with $\text{Hom}(\mathbb{C}^n / S, S)$, we obtain $X \backslash \!/ G = T^*\text{Gr}$.

Consider now the abelian quotient. The $T$-semistable points are the pairs $(S, Q)$ as above where no row of $S$ vanishes; $\mu_T^{-1}(0)$ consists of pairs $(S, Q)$ where the diagonal of $Q \cdot S$ vanishes. Dividing by the $T$ action we obtain the claim.
The general case

For \( r > 1 \), we can write the zero section \( F \subseteq X_G \) as the Kähler quotient

\[
\bigoplus_{i=1}^r \text{Hom}(\mathbb{C}^{k_i}, \mathbb{C}^{k_{i+1}})/G.
\]

Corresponding to the description of \( F \) as a tower of Grassmannians, its abelianization \( F_T \) is a toric variety which can be described as a tower of products of projective bundles [1]:

\[
(P^{k_{i+1}-1})^{k_i} \longrightarrow F^i_T \quad = \quad \mathbb{P}(V_{i+1} \times F^{i+1}_T \cdots \times F^{i+1}_T \mathbb{P}(V_{i+1})
\]

where \( F^i_T \) is the abelianization of \( F(k_i, \ldots, k_r, n) \), and

\[
V_{i+1} = \bigoplus_{j=1}^{k_{i+1}} \mathcal{O}_{F^{i+1}_T}(0, \ldots, 0, -1, 0, \ldots, 0)
\]

is the vector bundle on \( F^{i+1}_T \) corresponding to the tautological bundle on \( F^{i+1} \).

The hyperkähler abelianization \( X_T \) contains \( T^*F_T \) as a dense open subset, and we have further \( X_G^{ss} \subseteq T^*F_T \). \( X_T \) is obtained by gluing together flopped versions of \( T^*F_T \), but we do not give a full description here.

5.1.3 Torus fixed points

Take \( A_0 = (\mathbb{C}^*)^n \), acting on \( F \) through its natural action on \( \mathbb{C}^n \) and on \( X_G \) symplectically. Let \( \mathbb{C}^* \) act on \( X_G \) by scaling the fibers with weight \( h \), and put \( A = A_0 \times \mathbb{C}^* \). We choose the chamber corresponding to a cocharacter of \( A_0 \) acting with distinct weights \( \lambda_1 > \lambda_2 > \ldots > \lambda_n \). The stable leaves are conormal bundles to Schubert cells.

Fixed points in \( X_G \) correspond to flags where each subspace is spanned by coor-
ordinate axes. The number of fixed points is

\[
\begin{pmatrix}
\begin{array}{c}
\vdots \vline \\
1 \vline \\
1 \vline \\
\vdots \\
\end{array}
\end{pmatrix}
\frac{n}{k_1, k_2 - k_1, \ldots, n - k_r} = \begin{pmatrix}
\begin{array}{c}
\vdots \vline \\
k_2 \vline \\
k_1 \vline \\
\vdots \\
\end{array}
\end{pmatrix}
\frac{n}{k_1} \frac{k_2}{k_1} \cdots \frac{n}{k_r}.
\]

We use two ways to index a fixed point \( P \), corresponding to the RHS and LHS above:

1. The ‘quiver’ notation by subsets \( p^l \subseteq \{1..k_{l+1}\} \), \( l = 1..r \) of order \( k_{l+1} \). We put \( p^{r+1} = \{1..n\} \).

2. The ‘flag’ notation by subsets

\[ p^1 \subset p^2 \subset \ldots \subset p^r \subset p^{r+1} = \{1..n\} \]

of order \( k_1, k_2, \ldots, k_r, n \).

These are related by

\[ p'_l = p^{l+1}_{p'_l}. \quad (5.2) \]

As one might expect, and we show below, fixed point lifts in \( X_T \) are also discrete, indexed by a choice of ordering on each \( p^l \). The \( l \)-th factor of \( W \) acts on \( p^l \) by permuting the factors and on \( p^{l-1} \) through its action on \( \{1..k_l\} \), and by its action on \( p^l \) alone in the flag notation. Choosing the Borel of upper triangular matrices in all factors of \( G \), the dominant lift is given by taking the ascending order on each subset.

5.2 Abelianization of the stable basis

5.2.1 The stable basis in the abelian quotient

Let \( t^N = \bigoplus_{i=1}^r \text{Hom}(\mathbb{C}^{k_i}, \mathbb{C}^{k_{i+1}}) \), \( t^K = \text{Lie}(T) \) (corresponding to the tori denoted \( t^a, t^k \) in chapter 3), \( t^d = t^N / t^K \). Recall the notation \( (z_{ij}^d, w_{ij}^d) \) for the coordinates of \( T^*t^N \). In accordance with our previous notation, we also denote by \( e_{ij}^d \) the standard generators.
on $t^N$, $\epsilon^l_{ij}$ the dual basis, $u^l_{ij}$ the associated tautological classes on $X_T$.

The fixed point $P$ indexed in the quiver notation corresponds to the intersection of all hyperplanes except $u^l_{i,p^l_i}$. Let $a^l_{ij}, j \neq p^l_i$ be the normals to the hyperplanes defining $P$; these span $t^d$. Denote by $\alpha^l_{ij}$ be the dual basis. The coordinate $t^l_i$ of $t^K$ embeds in $t^N$ as $-\sum_j \epsilon^{l-1}_{ji} + \sum_j \epsilon^l_{ij}$. Identifying $(t^d)^*$ with its image in $(t^N)^*$ as usual, we have

$$a^l_{ij} = \epsilon^l_{ij} - \epsilon_{i,p^l_i}^l + \epsilon_{j,p^l_{j+1}}^{l+1}.$$  \hfill (5.3)

Considering the dominant lift $\hat{P}$ of $P$ and using the flag notation, the weight of $a^l_{ij}$ under the $A_0$ action is

$$\lambda_{p^l_{j+1}} - \lambda_{p^l_i}$$

as can be readily seen by induction. In particular, if the $\lambda$-s are distinct there are no zero weights and the lifts are discrete as claimed. It is also easy to see that this weight is negative iff $j < p^l_i$ (now in the quiver notation!). Recall the star notation from (3.4); the polarization induced from the quotient structure matches the polarization (3.11) and we conclude that the stable envelope is given by

$$\text{stab}_T(\hat{P}) = \prod_i \prod_{j, l} (u^l_{ij})^{s(j-p^l_i)}.$$  \hfill (5.4)

### 5.2.2 Abelianization

**Roots**

The $T$ orbit corresponding to the fixed point $P$ is spanned by the coordinates $z_{i,s_i}^l$. Induction again shows that the identification of the $A$ action as a subtorus of $T$ is given by

$$\Phi_P(\lambda_1, ..., \lambda_n) \mapsto (\lambda_{p^l_1}, ..., \lambda_{p^l_{s_1}}), ..., (\lambda_{p^l_{s_i}}, ..., \lambda_{p^l_{s_r}})$$
The root \((ij)\) of the \(l\)-th factor in \(G\) is therefore given by

\[
\lambda_{p'_l} - \lambda_{p'_j},
\]

proving also that the ascending order on \(S\) gives the dominant lift as claimed.

**Fixed point restriction**

We now compute the restrictions of tautological classes to fixed points, using (3.3.2). Since there are no \(w\) coordinates in the \(T\) orbit corresponding to \(P\), it follows from (3.9) that \(h\) does not appear in the restriction. Let \(\sigma = (\sigma_1, ..., \sigma_r) \in W\) and let \(\sigma \hat{P}\) be the corresponding lift. Then restricting from \(T^d\) to \(A\)-equivariant cohomology, we obtain

\[
u^l_{ij}|_{\sigma P} = \lambda(p_{\sigma_j}^{l+1}) - \lambda(p_{\sigma_i}^l).
\]

(5.6)

Note that the restriction vanishes when \(\nu^l_{ij}\) is not one of the defining hyperplanes, as required.

**Abelianization formula**

Applying (5.2–5.6) to our abelianization formula (4.3.3), we obtain:

**Theorem 5.2.1.** Let \(P = (p^l), Q = (q^l)\) be \(A\) fixed points in \(T^* \mathcal{F}\). Then

\[
\text{stab}(T^* \mathcal{F}, P)|_Q = \sum_{\sigma_1, ..., \sigma_r} \prod_{i=1, j=k_{i+1}}^{r} \left( \lambda(q_{\sigma_j}^{l+1}) - \lambda(q_{\sigma_i}^l) \right) \cdot \left( h + \lambda(q_{\sigma_i}^l) - \lambda(q_{\sigma_j}^l) \right)
\]

were the sum is over \(\sigma^i \in S_{k_i}\), and \(\sigma^{r+1} = \text{id}\).

**Remark 5.2.2.** In the recent paper [31], the authors obtain analogous formulas for the stable basis; while they to not provide an explicit restriction formula, their proof
involves a restriction argument. Their results originate from the quantum-integrable side of the theory, by means of certain weight functions, which play the role of our stab_T. They proceed to obtain the formulas for stab_G by explicit computation. Our derivation provides a geometric counterpart to theirs, and an interesting example of the interplay between the two sides of the Nekrasov-Shatashvili correspondence.

5.3 The Grassmannian case

One of the most basic examples of the Nekrasov-Shatashvili correspondence is between the inhomogeneous XXX spin chain and \( X = T^*Gr \). Under this identification, the stable basis corresponds to the coordinate (spin) basis, and the fixed-point basis corresponds to the Bethe eigenbasis at \( q = 0 \) (this follows from [22], though an equivalent statement was known to Nekrasov and Shatashvili). Our restriction formula therefore gives an explicit diagonalization of the Hamiltonian at \( q = 0 \). While this result is not new, we believe that our geometric derivation is of interest. We state the result for this case separately:

**Proposition 5.3.1.** Let \( X_G = T^*Gr(k, n) \), \( P = (p_1, ..., p_k) \), \( Q = (q_1, ..., q_k) \) two fixed points. Then

\[
\text{stab}(T^*Gr, P)|_Q = \sum_{\sigma \in S_k} \prod_{i=1}^{k} \left( \prod_{j=1}^{p_i-1} (h - \lambda_j + \lambda_{q_{\sigma(i)}}) \cdot \prod_{j=p_i+1}^{n} (\lambda_j - \lambda_{q_{\sigma(i)}}) \right) \prod_{1 \leq j < i \leq k} (\lambda_{q_{\sigma(i)}} - \lambda_{q_{\sigma(j)}}) \cdot \prod_{1 \leq j < i \leq k} (h + \lambda_{q_{\sigma(i)}} - \lambda_{q_{\sigma(j)}})
\]

These are the rational Schur polynomials, introduced by Rains [30] as part of a broader family of rational interpolation polynomials.

**Remark 5.3.2.** We can use this result to recover the fixed point restriction of equivariant Schubert classes in the Grassmannian [16, 18], given by factorial Schur polynomials ([20], 1.3.20), by taking the limit \( h \to \infty \) as follows. Let \( \Omega(p) \) be the Schubert
class in $Gr(k,n)$ corresponding to $p$. Then up to sign,

$$
\Omega(p)|_q = \lim_{k \to \infty} \frac{\text{stab}(T^*Gr, p)|_q}{h^{\dim \Omega(p)}}
$$

Since this restriction might be computed by taking semismall resolutions, we are using here the fact that for Grassmannians, the transition between the conormal basis and the stable basis is given by Kazhdan-Lusztig numbers ([6], see also 2.2.3).
Chapter 6

Abelianization for $\text{Hilb}_n \mathbb{C}^2$ and Symmetric Polynomials

In this chapter we apply our abelianization formula to $\text{Hilb}_n$, the Hilbert scheme of $n$ points on $\mathbb{C}^2$. Under the identification of the cohomology ring of $\text{Hilb}$ with symmetric functions, the fixed point basis and the stable basis are mapped to Jack polynomials and Schur polynomials respectively. Thus, we obtain a formula (6.3.6) expressing Schur polynomials in the Jack basis. To the author’s knowledge, this is the first formula of its kind.

6.1 Stable basis of $\text{Hilb}_n$

6.1.1 Hyperkähler quotient

We begin by recording a few basic facts about $\text{Hilb}_n$; more detail can be found in e.g. [26]. Recall that this is the Nakajima variety corresponding to the quiver with a single vertex and one edge loop. It is expressed as the hyperkähler quotient

$$\text{Hilb}_n = (X,Y,i,j) // \text{GL}(n),$$

(6.1)
where $X, Y \in \text{Hom}(\mathbb{C}^n, \mathbb{C}^n)$, $i \in \text{Hom}(\mathbb{C}, \mathbb{C}^n)$, $j \in \text{Hom}(\mathbb{C}^n, \mathbb{C})$. The GL action and the moment map are given by

$$g(X, Y, i, j) = (gXg^{-1}, gYg^{-1}, gi, jg^{-1})$$

$$\mu : (X, Y, i, j) \mapsto [X, Y] + ij$$

Choosing the character $\theta = \det \text{GL}(n)$ as the stability parameter, the stability condition reads: $i$ is a cyclic vector for the action of $X, Y$, and $j = 0$. In particular, on the stable locus the moment map restricts to $[X, Y]$. The isomorphism with $\text{Hilb}_n$ is made explicit by sending a codimension $n$ ideal $\mathcal{I}$ to the action of $x, y$ on $\mathbb{C}[x, y]/\mathcal{I}$ and the inclusion $i : 1 \rightarrow \mathbb{C}[x, y]/\mathcal{I}$.

**Torus action**

Let $A \cong (\mathbb{C}^*)^2$ act on $\mathbb{C}^2$ with weights $t_1, t_2$, and the induced action on $\text{Hilb}_n$. The weight of the symplectic form under this action is

$$h = t_1 + t_2$$

and its stabilizer is the subtorus $A_0 \cong \mathbb{C}^*$ acting with opposite weights. The fixed point locus is discrete, consisting of monomial ideals indexed by partitions of $n$, where the partition $\lambda = (\lambda_1, \lambda_2, ..., \lambda_k)$ corresponds to the ideal

$$\mathcal{I}_\lambda = \langle x^{\lambda_1}, x^{\lambda_2}y, ..., x^{\lambda_k}y^{k-1}, y^k \rangle.$$ 

### 6.1.2 Stable basis

We now explain the identification of the fixed point and stable bases with Jack and Schur polynomials. These results in fact predate the definition of the stable basis;
see, e.g. [32, 24, 19]. For notational consistency, we follow the treatment in [22], 17.2. Identifying the Nakajima operator $\alpha_{-k}$ acting on the $y$-axis with multiplication by the power-sum polynomial $p_k$, we obtain the standard isomorphism

$$H^*_A(\text{Hilb}) \cong \Lambda \otimes H^*_A(pt)$$

(6.2)

where $\Lambda$ is the ring of symmetric polynomials and

$$\text{Hilb} = \bigcup_n \text{Hilb}_n.$$

In [22], the standard inner-product on cohomology is twisted by a sign corresponding to what is called in loc. cit. the “canonical theta characteristic”. Transporting this to cohomology, we obtain the Jack inner product

$$\langle p_k, p_l \rangle = \delta_{kl} k(-t_1/t_2)$$

with parameter $-t_1/t_2$, denoted $\alpha$ in [20]. By definition, Gram-Schmidt orthogonalization of this inner product with respect to the basis $\{m_\lambda\}$ of monomial symmetric functions gives the Jack polynomials. On the other hand, the orthogonality relations on the fixed point basis imply that up to suitable normalization, these are the same. We define

$$J_\lambda = t_2^{\lvert \lambda \rvert} \cdot J_\lambda$$

(6.3)

where $J_\lambda$ is the integral Jack polynomial defined in [20]. This normalization implies

$$J_\lambda = \prod_{\square \in \lambda} (t_2(l(\square) + 1) - t_1 a(\square)) m_\lambda + \ldots$$

(6.4)
where

\[ l(\square) = \lambda_j^i - i \quad \quad \quad \quad a(\square) = \lambda_i - j \]

are the leg length and arm length of a box \( \square = (i, j) \) in \( \lambda \). Then we have

**Proposition 6.1.1** ([32, 24, 19]). *Under the identification (6.2), \( J_\lambda \) is the class of the fixed point \( [I_\lambda] \).*

We now consider the stable basis, under the chamber

\[ C = \{ t_1 < 0 \} \]

of \( A_0 \), and the polarization defined by the Euler class of \( N_- \) at \( I_\lambda \), where we identify the product in (6.4) with the Euler class of \( N_+ \). The induced order on partitions is the dominance order, and we have

**Proposition 6.1.2** ([32]). *Under the identification (6.2), the Schur polynomial \( s_\lambda \) is the class of the stable envelope of \( [I_\lambda] \).*

The proof is immediate, since Schur polynomials are triangular with respect to Jack polynomials, and proportional to them modulo \( \hbar \); (6.4) fixes the normalization.

### 6.2 The Hypertoric Hilbert Scheme

We define the hypertoric Hilbert scheme to be the abelianization of \( \text{Hilb} \), i.e. the quotient

\[ \text{THilb} = (X, Y, i, j) // T^n, \]

where \( T^n \leq \text{GL}_n \) is the diagonal torus. This is a rather interesting, if little studied, hypertoric variety, and we digress briefly to mention a few basic details about it. We...
do not have a moduli theoretic interpretation of THilb, and it would be an interesting problem to find one.

6.2.1 Hyperplane arrangement

In our hypertoric notation, we write

\[ \text{THilb} = T^*\mathbb{C}^{n^2+n} // T^n. \]

Writing as usual \((z, w)\) for the coordinates of \(T^*\mathbb{C}^{n^2+n}\), the \(z\) coordinates correspond to \(X, i\), and the \(w\) coordinates correspond to \(Y^t, j\).

The torus \(t^n = \text{diag}(\kappa_1, ..., \kappa_n)\), corresponding to \(t^k\) in the notation of chapter 3, acts with weight \(\kappa_i - \kappa_j\) on the coordinate \(z_{ij} = X_{ij}\), and weight \(\kappa_i\) on the coordinate \(z^fr_i = i\). We denote the tautological classes associated with \(z_{ij}\) by \(u_{ij}\), and those associated with \(z^fr_i\) by \(u^fr_i\). The torus \(A\) acts as a subtorus of \(T^{n^2+n}\), with the weight \(t_1\) on the coordinates \(z_{ij}\) and 0 on the coordinates \(z^fr_i\).

We denote the coordinates of \(t^{n^2+n}\) by \(e_{ij}, e^fr_i\); the dual basis by \(\epsilon\); and the image of the coordinates \(e\) in the quotient torus \(T^d = T^{n^2+n} / T^n\) by \(b\) (here we depart from the notation of chapter 3 to reserve the letter \(a\) for partition arm length). Once a basis for \(T^d\) or its subtorus has been chosen, the dual coordinates are denoted by \(\beta\).

The stability parameter is \(\sum \kappa_i\), and lifts to the character \(\sum i \epsilon^fr_i\) of \(t^{n^2+n}\). Choosing the images of the \(e_{ij}\) coordinates as a basis for \(T^d\) we have

\[ \beta_{ij} = \epsilon_{ij} - \epsilon^fr_i + \epsilon^fr_j \]

Under this notation, we obtain the \(n^2 + n\) hyperplanes

\[ b_{ij} = 0 \quad \sum_j b_{ij} - b_{ji} + 1 = 0 \]
Example 6.2.1. Let $n = 2$. Splitting away the diagonal factor corresponding to the hyperplanes $b_{ii}$, we obtain the arrangement described in example (3.1.2). The Weyl group action is given by the reflection along the $b_{12} = b_{21}$ diagonal.

Circuits

An easy calculation shows that there are $2^n - 1$ circuits in the arrangement: for every non-empty subset $S \subseteq \{1..n\}$, the following is a minimal relation:

$$\sum_{i \in S} b_i^{fr} + \sum_{i \in S} b_{ij} - \sum_{i \in S} b_{ij}.$$ (6.5)

6.2.2 Geometry of THilb

Cohomology

Using (3.1.5, 6.5) we conclude:

Proposition 6.2.2. $H^*_{T_{\mathbb{C}^*}^{\mu_T}}(\text{THilb})$ is generated by $u_{ij}, u_i^{fr}, h$ subject to the relations:

$$\prod_{i \in S} u_{ij} \prod_{i \notin S} (h - u_{ij}) \prod_{i \in S} u_i^{fr} \quad \forall S \subseteq \{1..n\}, S \neq \emptyset$$

Stability

The stability conditions for a point in $\mu_T^{-1}(0)$ are explained in [17]. Briefly, for each circuit one obtains a condition on the vanishing of some of the coordinates $z, w$. We do not give the full details here, and instead state directly the application for THilb: $(z, w) \in \mu_T^{-1}(0)$ is stable iff for every nonempty $S \subseteq \{1..n\}$, at least one of the following coordinates does not vanish:

$$z_{ij} \quad (i \in S, j \notin S); \quad w_{ij} \quad (i \notin S, j \in S); \quad z_i^{fr} \quad (i \in S).$$
Equivalently,

**Proposition 6.2.3.** $(X, Y, i, j) \in \mu_T^{-1}(0)$ is stable iff any subspace containing $i$ and stable under $X, Y$ is not contained in any coordinate hyperplane.

### 6.3 Abelianization

#### 6.3.1 Fixed point loci in $THilb$

Let $I_\lambda \in \text{Hilb}_n^\lambda$, and let $V_\lambda = \mathbb{C}[x, y]/I_\lambda$. The $W = S_n$ action permutes the monomial basis for $V_\lambda$; this is equivalent to a Young tableau of shape $\lambda$. It will be convenient to write the $T^n$ weights in the appropriate box, as in the example below. We use zero based coordinates for boxes; we call the top left box $o = (0, 0)$ the *origin* of $\lambda$. For the box $i = (i_y, i_x)$ let

$$p(i) = p_\lambda(i) = i_y - i_x;$$

writing partitions in the “Russian” convention, rotated by $45^\circ$, this is the projection to the horizontal axis. We will see that for the Borel of lower triangular matrices (since we chose the chamber $t_1 < 0$), the dominant lift corresponds to any ordering compatible with $p$. We choose such an ordering, increasing along the diagonals, as our reference.

**Example 6.3.1.** We will use the partition $\lambda = (3, 3)$ as a running example; e.g., we write the $T$ action on $V_\lambda$ as

$$
\begin{array}{ccc}
\kappa_4 & \kappa_2 & \kappa_1 \\
\kappa_6 & \kappa_5 & \kappa_3 \\
\end{array}
$$

In this example the coordinates of the box labeled 1 are $(0, 2)$. 

58
Consider the lift of $\lambda$ to data $X,Y,i$ as in (6.1) such that

\[
X_{ij} = z_{ij} \neq 0 \quad \text{iff} \quad i_y = j_y, \quad j_x = i_x - 1 \\
Y_{ij} = w_{ji} \neq 0 \quad \text{iff} \quad i_x = j_x, \quad j_y = i_y + 1
\]

Since the $A$-weights of $i = z^f$ are 0, one checks that under the associated embedding $\Phi_\lambda : A \to T$, the box $i$ must have weight $i_xt_1 + i_yt_2$. The root $(i,j)$ on $A_0$ evaluates to $(p(j) - p(i))t_1$, so that the roots in the centralizer $G_\lambda$ of $A_0$ are those associated with pairs of boxes along a diagonal. We denote the corresponding Weyl group $W_\lambda$. From this argument it is also clear that the lift we have picked is indeed the dominant lift when $t_1 < 0$ (see figure below). Finally, $A$ embeds into $T$ with distinct weights, so no roots vanish on it; therefore

**Observation 6.3.2.** *In the diagram (4.1), the fixed points along the fiber of $\pi$ are discrete, and therefore (3.3.4) applies.*

**Example 6.3.3.** For $\lambda = (3,3)$, $\Phi_\lambda$ is given by

<table>
<thead>
<tr>
<th></th>
<th>$t_1$</th>
<th>$2t_1$</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>$t_1$</td>
<td>$2t_1$</td>
</tr>
<tr>
<td>$t_2$</td>
<td>$t_1 + t_2$</td>
<td>$2t_1 + t_2$</td>
</tr>
</tbody>
</table>

Explicitly, restricting to $A_0$ with $t_1 = -1$:

<table>
<thead>
<tr>
<th></th>
<th>$-1$</th>
<th>$-2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>$-1$</td>
</tr>
</tbody>
</table>

$G_\lambda$ contains the positive roots $(3,2)$ and $(5,4)$.

Let $\tilde{I}_\lambda$ be a lift of $I_\lambda$ to $THilb$. By the abelianization lemma (4.2.3), this is the hypertoric variety obtained from $THilb$ by restricting to the hyperplanes where the $A_0$ action is compatible with $\Phi_\lambda(A_0)$. These are the coordinates $e_{ij}$ where $p(j) = p(i) + 1$.  

59
and the coordinates \( e^f_i \) with \( p(i) = 0 \). In the language of [22], the point \( \mathcal{I}_\lambda \) is written as a type \( A \) quiver variety with vertices indexed by the weights of \( A_0 \), framed at 0, with edges between consecutive weights, and dimension vector given by the weight multiplicity. The lift is the abelianization of this quiver.

**Example 6.3.4.** For \( \lambda = (3, 3) \) the dominant lift is obtained by restricting the arrangement of \( THilb \) to the coordinates indicated in the figure.

\[
\begin{array}{c}
\cdots \bullet \cdots \\
\cdots \bullet \bullet \cdots \\
\cdots \bullet \bullet \bullet \cdots \\
\cdots \bullet \bullet \bullet \bullet \cdots \\
\cdots \bullet \bullet \bullet \bullet \bullet \cdots \\
\end{array}
\]

\[
\begin{array}{c}
\cdots \bullet \cdots \\
\cdots \bullet \bullet \cdots \\
\cdots \bullet \bullet \bullet \cdots \\
\cdots \bullet \bullet \bullet \bullet \cdots \\
\cdots \bullet \bullet \bullet \bullet \bullet \cdots \\
\end{array}
\]

\[
\begin{array}{c}
\cdots \bullet \cdots \\
\cdots \bullet \bullet \cdots \\
\cdots \bullet \bullet \bullet \cdots \\
\cdots \bullet \bullet \bullet \bullet \cdots \\
\cdots \bullet \bullet \bullet \bullet \bullet \cdots \\
\end{array}
\]

Note that we have 10 hyperplanes, and dividing by \( T^6 \),

\[
\dim \tilde{\mathcal{I}}_\lambda = 2 \cdot (10 - 6) = 2 \dim(G_\lambda/T)
\]

as expected. Alternatively, the lift corresponds to the abelianization of the Nakajima quiver

\[
\begin{array}{c}
1 \quad 2 \quad 2 \quad 1 \\
\end{array}
\]

where the indicated dimensions correspond to the multiplicities of the weights \(-2, -1, 0, 1\).
6.3.2 Fixed point restriction and the stable basis of THilb

Fixed point restriction

Following (4.3.4) we study the $A$-equivariant restriction of tautological classes to the lift (6.6), thought of as an $A$-fixed point in $\tilde{I}_\lambda$. The normals to the defining hyperplanes for $\tilde{I}_\lambda$ form a basis for its stabilizing torus, call it $T^Q$. These are the $b_{ij}$ where $p(j) \neq p(i) + 1$, and $b^r_i$ with $p(i) \neq 0$. The dual basis is given as follows. Choose a path $j = j_0, j_1, ..., j_m = i$ in the diagram $\lambda$ such that the boxes $j_k, j_{k+1}$ are adjacent. Let

$$
\epsilon^*_{j_k, j_{k+1}} = \begin{cases} 
\epsilon_{j_k, j_{k+1}} & \text{if } p(j_{k+1}) = p(j_k) + 1 \\
-\epsilon_{j_{k+1}, j_k} & \text{if } p(j_{k+1}) = p(j_k) - 1 
\end{cases}
$$

Then we have

$$
\beta_{ij} = \epsilon_{ij} + \epsilon^*_{j, j_1} + \epsilon^*_{j_1, j_2} + ... + \epsilon^*_{j_{m-1}, j_m}.
$$

This is easy to check keeping in mind that $b^{fr}_i$ is the image in $t^d$ of $\sum_j e_{ji} - e_{ij}$. One also sees in a similar manner that as a basis for $(t^Q)^*$ this is independent of the chosen path, i.e. that any closed path in $\lambda$ kills $t^Q$. Similarly, let $j$ be any box such that $p(j) = 0$. For convenience we choose $j = o$, the origin. Choose a path $i = i_0, i_1, ..., i_m = o$ as above. Then

$$
\beta^{fr}_i = \epsilon^*_{i, i_1} + \epsilon^*_{i_1, i_2} + ... + \epsilon^*_{i_{m-1}, o}.
$$

Applying the restriction rules (3.10) and using (3.9), we see that we also get a contribution of $-h$ from every vertical step in the chosen paths.
Introduce the following notation for the relative arms and legs of two boxes $i, j$ in $\lambda$:

$$
a_{ij}^\lambda = j_x - i_x \\
l_{ij}^\lambda = j_y - i_y
$$

Restricting to $A$ weights sends any $\epsilon_{ij}$ to $t_1$, and since $h = t_1 + t_2$, we obtain:

$$
u_{ij}|_{\tilde{\mathcal{I}}_\lambda} = (1 + a_{ij}^\lambda)t_1 + l_{ij}^\lambda t_2 = h^\lambda(i, j)$$

$$
u_1|_{\tilde{\mathcal{I}}_\lambda} = a_{i, o}^\lambda t_1 + l_{i, o}^\lambda t_2$$

These are the restrictions to dominant lifts; the other lifts are obtained by applying the $W$ action. For $\sigma \in W$ we write $a_{ij}^{\sigma \lambda} = a_{\sigma^i, \sigma^j}^{\lambda}$ etc.

**Stable basis of $\text{THilb}$**

Taking $t_2 = -t_1$ and applying the results of the previous section for the defining hyperplanes of $\tilde{\mathcal{I}}_\lambda$ we obtain their $A_0$ weights. Since we only need their signs, we take $t_1 = -1$. These are given by

\[
1 + p(i) - p(j) \quad \text{on} \quad b_{ij} \\
p(i) \quad \text{on} \quad b_i^{fr}.
\]

Note how these vanish precisely on the defining hyperplanes.
**Example 6.3.5.** For $\lambda = (3, 3)$, these weights are

\[
\begin{pmatrix}
1 & 0 & 0 & -1 & -1 & -2 \\
2 & 1 & 1 & 0 & 0 & -1 \\
2 & 1 & 1 & 0 & 0 & -1 \\
3 & 2 & 2 & 1 & 1 & 0 \\
3 & 2 & 2 & 1 & 1 & 0 \\
4 & 3 & 3 & 2 & 2 & 1 \\
\end{pmatrix}
\begin{pmatrix}
-2 & -1 & -1 & 0 & 0 & 1 \\
\end{pmatrix}
\]

Recall the star notation (3.4). We conclude from (3.3.5) that in the chamber $t_1 < 0$,

\[
\text{stab}(\text{THilb}, \lambda) = \prod_{1 \leq i,j \leq n} u_{ij}^{(1 + p(i) - p(j))} \prod_{1 \leq i \leq n} (u_i^{fr})^{p(i)} \tag{6.8}
\]

**Roots**

The last ingredient needed for our abelianization formula is the roots. From the discussion in (6.3.1), the root $(i, j)$ is given by

\[
a_{ij}t_1 + l_{ij}t_2.
\]

**6.3.3 Schur polynomials and Jack polynomials**

Recall that in Hilb, the stable basis corresponds to Schur polynomials and the fixed-point basis corresponds to Jack polynomials. Let

\[
N_\lambda = \prod_{\square \in \lambda} (t_2(l(\square) + 1) - t_1a(\square)) \cdot (t_2l(\square) - t_1(a(\square) + 1))
\]

be the product of normal weights to Hilb_n at $\lambda$. Since $J_\lambda$ are the classes of fixed points in $H_\lambda^*(\text{Hilb})$, the restriction formula will give us the coefficients of $J_\lambda/N_\lambda$ in the expansion of Schur polynomials. Up to a constant factor, this is known as the
“C” normalization of Jack functions.

Plugging in the results of the previous section, our restriction formula (4.3.3) gives:

**Theorem 6.3.6.** Let

\[ s_\lambda = \sum c_{\lambda,\nu} J_\nu / N_\nu. \]

Then

\[ c_{\lambda,\nu} = \sum_{\sigma \in W/W_\lambda} \prod_{i, j=1}^n \frac{(1 + a_{ij}^{\sigma_\nu}) t_1 + l_{ij}^{\sigma_\nu} t_2)^{(1 + a_{ij}^{\sigma_\nu} - l_{ij}^{\sigma_\nu})} \prod_{i=1}^n (a_{i,\sigma_\nu}^{\sigma_\nu} t_1 + l_{i,\sigma_\nu}^{\sigma_\nu} t_2)^{(1 - a_{i,\sigma_\nu}^{\sigma_\nu} + l_{i,\sigma_\nu}^{\sigma_\nu})}}{\prod_{a_{ij}^{\sigma_\nu} \neq l_{ij}^{\sigma_\nu}}_{j < i} (a_{ij}^{\sigma_\nu} t_1 + l_{ij}^{\sigma_\nu} t_2)^{(1 + a_{ij}^{\sigma_\nu}) t_1 + (1 + l_{ij}^{\sigma_\nu}) t_2}} \]

We remind the reader that terms whose numerator is 0 are discarded even if the denominator vanishes.
